QUO WARRANTO, in English law, the name given to an ancient prerogative writ calling upon any person usurping any office, franchise, liberty or privilege belonging to the Crown, to show “by what warrant” he maintained his claim, the onus being on the defendant. It lay also for non-user or misuser of an office, &c. If the Crown succeeded, judgment of forfeiture or ousterlemain was given against the defendant. The procedure was regulated by statute as early as 1278 (the statute of Quo Warranto, 6 Edw. I. c. 1), passed in consequence of the commission of quo warranto issued by Edward I. A distinction has been drawn in the report between liberties, jurisdiction exercised by the lord as lord, and regalia, jurisdiction exercised by Crown prerogative. After a time the cumbersome and inconvenience of the ancient practice led to its being superseded by the modern form of an information in the nature of a quo warranto, exhibited in the King’s Bench Division, either by the attorney-general ex officio or by the king’s coroner, and not at the instance of a private person called the relator. The writs of quo warranto will not be issued except by leave of the court on proper cause being shown. It does not lie where there has been no user or where the office has determined. Nor does it lie for the usurpation of every kind of office. But it lies where the office is of a public nature and created by statute, even though it is not an encroachment upon the prerogative of the Crown. Where the usurpation is of a municipal office the information is regulated by 9 Anne c. 25 (1711), under which the defendant may be fined and judgment of ouster given against him, and costs may be granted for or against the relator. Such an information must, in the case of boroughs within the Municipal Corporations Act 1882, be brought within twelve months after disqualification (s. 225); in the case of other boroughs, within six years after the defendant first took upon himself the office (32 Geo. III. c. 58, s. 2). The information in the nature of a quo warranto, though nominally a criminal, has long been really a civil proceeding, and has recently been expressly declared to be so (Supreme Court of Judicature Act 1884, s. 15). In cases not falling within 9 Anne c. 25, judgment of ouster is not usually given. The most famous historical instance of quo warranto was the action taken against the corporation of London by Charles II. in 1684. The King’s Bench adjudged the charter and franchises of the city of London to be forfeited to the Crown (State Trials, vol. viii. 1039). This judgment was reversed by 2 Will. & Marry, sess. 1, c. 8; and it was further enacted, in limitation of the prerogative, that the franchises of the city should never be seized or forejudged on pretence of any forfeiture or misdemeanour. In Scotland the analogous procedure is by action of declarator.

In the United States the right to a public office is tried by quo warranto or similar procedure, regulated by the state laws. Proceedings by quo warranto lie in a United States court for the removal of persons holding office contrary to art. xiv. s. 3 of the Amendments to the Constitution (act of the 31st of May 1870, c. 14).
THE twentieth letter in the Phoenician alphabet, the nineteenth in the numerical Greek, the seventeenth in the ordinary Greek and the Latin and (owing to the addition of J) the eighteenth in the English. Its earliest form in the Phoenician alphabet when written from right to left was א, thus resembling the symbol for D with one side of the triangle prolonged. In Aramaic and other Semitic scripts which were modified by opening the heads of the letters, the symbol in time became very much changed. Greek, however, maintained the original form with slight variations from place to place. Not infrequently in the Greek alphabets of Asia Minor and occasionally also in the West, R was written as ד, thus introducing a confusion with D (q.v.). Elsewhere a short tail was added, as occasionally in the island of Melos, in Attic, in Macedonia, and in western Greece, but nowhere does this seem to have been universal. The earliest Latin forms are exactly like the Greek. Thus in the very early inscriptions found in the Forum in 1890 R appears as Q (from right to left). P and D (from left to right). Later the forms R and R come in; sometimes the back is not quite connected in the middle to the upright, when the form R is produced. The name of the Semitic symbol is Rēṣh; why it was called the Greeks Rhō (ῥ) is not clear. The h which accompanies r in the transliteration of Greek ῥ, indicates that it was breathed, not voiced, in pronunciation. No consonant varies more in pronunciation than r. According to Brockelmann, the original Semitic r was probably a trilled r, i.e. an r produced by allowing the tip of the tongue to vibrate behind the teeth while the upper surface of the tongue is pressed against the sockets of the teeth. The ordinary English r is also produced against the sockets of the teeth, but without trilling; another r, also untrilled, which is found in various parts of the south of England, is produced by turning up the tip of the tongue behind the sockets of the teeth till the tongue acquires something of a spoon shape. This, which is also common in the languages of modern India, is called the cerebral or cacuminal r, the former term, which has no meaning in this connexion, being only a bad translation of a Sanscrit term. The common German r is produced by vibrations of the uvula at the end of the soft palate, and hence is called the uvular r. There are also many other varieties of this sound. In many languages r is able to form syllables by itself, in the same way that l, m, n may do, as in the English brittle (britt), written (rit). In Europe r with this value is most conspicuous in Slavonic languages like Bohemian (Czech) and Croatian; in English r in this function is replaced by a genuine vowel in words like mother (mother). This syllabic r is first recorded for Sanscrit, where it is common, but is replaced in the languages descended from Sanscrit by a r and a vowel or by a vowel only, according to the position in which it occurs. Most philologists are of opinion that syllabic r existed also in the mother-tongue of the Indo-European languages.

RAABE, HEDWIG (1844-1905), German actress, was born in Magdeburg on the 3rd of December 1844, and at the age of fourteen was playing in the company of the Thalia theatre, Hamburg. In 1864 she joined the German Court theatre at St Petersburg, touring about Germany in the summer with such success that in 1868 she relinquished her Russian engagement to devote herself to starring. In 1871 she married Albert Niemann (b. 1883), the operatic tenor. She excelled in classical roles like Marianne in Goethe's Geschichte and Franziska in Minna von Barnhelm. It was she who first played Ibsen in Berlin. She died on the 21st of April 1905.

RAABE, WILHELM (1831-1910), German novelist, whose early works were published under the pseudonym of Jakob Corvinus, was born at Eschershausen in the duchy of Brunswick on the 8th of September 1831. He served apprenticeship at a bookseller's in Magdeburg for four years (1849-1854); but fitting of the routine of business, studied philosophy at Berlin (1855-1857). While a student at that university he published his first work, Die Chronik der Spritungsägasse (1857), which at once attained to great popularity. Raabe next returned to Wolfenbüttel, and then lived (1862-1870) at Stuttgart, where he devoted himself entirely to authorship and wrote a number of novels and short stories; notably Unseres Herrgotts Kanzel (1862); Der Hungerpastor (1864); Aba Teljm (1867) and Der Schüdderump (1870). In 1870 Raabe removed to Brunswick and published the narratives Horacker (1876)—perhaps his masterpiece; Das Obfeld (1889); Kloster Lugau (1894) and Hastenbeck (1899), and numerous other stories. The distinguishing characteristic of Raabe's work is a genial humour which reminds us occasionally of Dickens; but this humour is often combined with a pessimism that is foreign to the English novelists.

RABA BEN JOSEPH BEN HAMA (c. 280-357), Babylonian rabbi or amora. He is closely associated in his studies with Abaye. The latter was head of the Academy at Pumbeditha. Raaba founded a new school at Mahuza, which eventually became so long as Raaba lived the only academy in Babylonia (Persia). The development of Talmudic Law (or Halakhah) was much indebted to this rabbi, whose influence in all branches of Jewish learning was supreme. His friendship with the King Shapur II enabled Raba to secure a relaxation of the oppressive laws enacted against the Jews of Persia.

RABAH ZOEIR (d. 1900), the conqueror of Bornu (an ancient sultanate on the western shores of Lake Chad, included since 1890 in British Nigeria), was a half- Arab, half negro chieflain. He was originally a slave or follower of Zobeir Pasha (q.v.), and is said to have formed one of the party which served as escort to Miss Tinne (q.v.) in her journeys in the Bahr-el-Ghazal in 1862-64. In 1879, Zoeir being in Egypt, his son Suleiman and Raba were in command of Zoeir's forces in the Bahr-el-Ghazal. They persisted in slave-raiding, and denied the khedive's authority, and Colonel C. G. Gordon sent against them Romolo Gessi Pasha. Gessi captured Suleiman and routed Raba, who in July 1879 fled westward with some seven hundred Bazingirs (black slave soldiers). He made himself master of Ketric and Dar Banda, countries to the south and southwest of Wadai. In 1884-85 he was invited by Mahomed Ahmed (the mahdi) to join him at Omdurman, but did not do so. According to one account he learnt that the mahdi intended, had he gone to Omdurman, to put him to death. In 1891 Paul Crampe, a French explorer, was killed in Dar Banda by a chieflain tributary to Raba, and Crampe's stores, including 300 rifles, were sent to Raba. With this reinforement of arms he marched towards Wadai, but being stoutly opposed by the people of that country he turned west and established himself in Bagirmi, a state south-east of Lake Chad. In 1893 Raba overthrew the sultan of Bornu. In his administration of the country he showed considerable ability and a sense of public needs. To the British, represented by the Royal Niger Company, Raba gave comparatively little trouble. During 1894-95 he continually (but unavailingy) asked the company's representatives at Yola and Ibi to supply him with gunpowder. Raba then tried threats, and in 1896 all communication between him and the company ceased. Early in 1897 he began an advance in the direction of Kano, the most important city in the Fula empire. The news of the crushing defeat by Sir George Goldie of the Fula at Bida, and of the capture of Illorin, induced
Rabah to return to Bornu. He gave the British no further trouble, but turned his attention to the French. Emile Gentil had in this same year (1807) reached Lake Chad, via the Congo and Bagirmi, and had installed a French resident with the sultan of Bagirmi. As soon as Gentil had withdrawn, Rabah again fell upon Bagirmi, and forced sultan and resident to flee. In 1809 the French sent an expedition to reconquer the country, but at first they were unsuccessful. In the summer of 1809 Rabah attacked and routed the French advanced post, held by Naval-Lieutenant Bretonnet, and the latter was killed. In October following another battle was fought, in which the French, under Captain Robillot, completely defeated Rabah, who retreated north-east towards Wadal. Gathering a fresh army, he returned to Bagirmi and joined issue with the French a third time. In a battle fought on the 22nd of April 1800 Rabah was slain and his host defeated. The chieftain's head was cut off and taken to the French camp. In this engagement Major Lamy, the French commandant, also lost his life.

The French continued the campaign against Rabah's sons, two of whom were killed. Rabah had left instructions that if his army was finally defeated by the French, his successor should return to Bornu and make friends with the British. Rabah's third son, Fader-Allah, accordingly threw himself entirely upon British protection. He made a favourable impression, and it was contemplated to recognize him as sultan of Bornu. However, in the later part of 1801 Fader-Allah, who had 2500 riflemen, again made aggressive movements against the French. In retaliation, Captain Danegille pursued him into British territory. A battle was fought at Gujba, Fader-Allah being defeated. He fled mortally wounded, and died the same night, being buried in the bed of a small river, the course of which had been diverted for the purpose.

Connected accounts of Rabah's career are contained in É. Gentil's La Chute de l'empire de Rabah (Paris, 1902) and in M. von Oppenhein's Rabah und das Tschadseegebiet (Berlin, 1902). (F. R. C.)

RABAT (Rībāt), a city on the Atlantic coast of Morocco, in 34°3' N., 6°46' W., 130 m. S. of Cape Spartel, on the southern side and at the mouth of the Bu Ragrag, which separates it from Salli on the northern bank. It is a commercial town of about 26,000 to 30,000 inhabitants, occupying a rocky plateau and surrounded by massive but dilapidated walls, strengthened by three forts on the seaside side. To the south of the town stands a modern palace, defended by earthworks and Krupp guns. The conspicuous feature in the view from the ocean is the Borj el Hasan, an unfinished square-built tower, 145 ft. high, built on an elevation about 65 ft. above the sea to the west of the walled town. At one time the Bu Ragrag afforded a much better harbour than it does now; the roadstead is quite unprotected, and there is a dangerous bar at the mouth of the river, which hampers the shipping, and makes the growth of trade slow. The depth of water over the bar varies from 7 to 12 ft. Rabat trades with Fez and the interior of Morocco, with the neighbouring coast towns and Gibraltar, and with Marseilles, Manchester and London, and is the greatest industrial centre in Morocco.

Rabat was founded by Yakub el Mansur in 1184, but Salli was then already an ancient city, and on the scarped hills to the west of Rabat stand the ruins of Sala, a Roman colony, known as Sheilla. It contains a mausoleum of the Beni Mariin dynasty.

RABAUT, PAUL (1718-1794), French pastor of "the Church of the Desert" (see HEGEONOTS), was born at Bédarieux, near Montpellier, on the 29th of May 1718. In 1738 he was admitted as a preacher by the synod of Languedoc, and in 1740 he went to Lausanne to complete his studies in the seminary recently founded there by Antoine Court (q.v.). In 1741 Rabaut was placed at the head of the church of Nimes, and in 1744 he was vice-president of the general synod. During the persecution of 1745-1752 Rabaut himself was obliged to hide. When the marquis of Paulmy d'Argens was sent to Languedoc to make a military inspection, Rabaut succeeded in interviewing him (1750). For a time the persecution ceased, but it broke out again in 1753, a price being put upon Rabaut's head. Louis Francois de Bourbon, prince de Conti, interested himself in the Protestants in 1753, and in July Rabaut visited him. During the years 1755-1760 periods of persecution and toleration alternated. By the year 1760, however, the efforts of Antoine Court and P. Rabaut had been so successful that French Protestantism was well established and organized. Court de Gébelin, Paul Rabaut, and his son Saint-Étienne now exerted themselves to get it recognized by the law and government. When the people revolted, the minister Turgot in 1775 requested Rabaut to calm them. His success aroused the jealousy of his colleagues, who tried to undo the good work started by Antoine Court. But Rabaut persevered in his efforts to improve legally the position of the Protestants. In 1785, when he was visited by General La Fayette, it was arranged that Rabaut's son, Rabaut Saint-Étienne, should go to Paris on behalf of the Reformed Church. In November 1787 Louis XVI.'s edict of toleration was signed, though it was not registered until the 29th of January 1788. Two years later liberty of conscience was proclaimed by the National Assembly, of which Rabaut Saint-Étienne was chosen vice-president, and it was declared that non-Catholics might be admitted to all positions. After the fall of the Girondists, however, in which Rabaut Saint-Étienne was involved, Paul Rabaut, who had refused to renounce his title of pastor, was arrested, dragged to the citadel of Nimes, and kept in prison seven weeks (1794). He died at Nimes on the 25th of September 1794, soon after his release.

See J. Pons de Nimes, Notice biographique sur Paul Rabaut (1808); Charles Dardier, ses lettres à Antoine Court (1884) and Paul Rabaut, ses lettres à divers (1891).

RABAUT SAINT-ÉTIENNE, JEAN PAUL (1743-1793), French revolutionist, was born at Nimes, the son of Paul Rabaut (q.v.), the additional surname of Saint-Étienne being assumed from a small property near Nimes. Like his father, he became a pastor, and distinguished himself by his zeal for his co-religionists, working energetically to obtain the recognition of the civil rights which had been granted to them by Louis XVI. in 1788. Having gained a great reputation by his Histoire primitive de la Grèce, he was elected deputy to the States General in 1789 by the third estate of the baillage of Nimes. In the Constituent Assembly he worked on the framing of the constitution, spoke against the establishment of the republic, which he considered ridiculous, and voted for the suspensive veto, as likely to strengthen the position of the crown. In the Convention he sat among the Girondists, opposed the trial of Louis XVI., was a member of the commission of twelve, and was proscribed with his party. He remained in hiding for some time but was ultimately discovered and guillotined on the 5th of December 1793.

See J. A. Dartigue, Rabaut St-Étienne à l'Assemblée Constituante (Paris, 1901); and A. Lodé, "Correspondance de Rabaut St-Étienne" in La Révolution française (1898), "l'arrestation de Rabaut St-Étienne" in La Révolution française (1899). (See also the same review for 1900.) Les débats de Rabaut St-Étienne aux États Généraux et à la Convention in the Bulletin historique de la Société de l'histoire du protestantisme français (1901), also an Essai sur la vie de Rabaut St-Étienne (1893) separately published. An edition of the Lettres de Rabaut Saint-Étienne (2 vols., 1826) contains a notice by Collin de Pancy.

RABBAS, a town of British West Africa, in the province of Nupe, Northern Nigeria, on the left bank of the Niger, in 9°5' N., and 200 m. above the confluence of the Niger and the Benue. At the time of Richard Lander's visit in 1839 it was a place of 40,000 inhabitants and one of the most important markets in the country. In 1867 Gerhard Rohls found it with only 500 inhabitants. The town has somewhat recovered its position since the establishment of British rule in 1902.

RABBAB BAR NAHMANI (c. 270-330), a Babylonian rabbi or amora (q.v.). He was for twenty-two years head of the Academy at Pumbeditha. His great dialectic skill acquired
for him the epithet "uprooter of mountains." The Talmud owes much to this rabbi. He is said to have perished in a jungle into which he had fled from the officers of the Persian king.

RABBAN BAR SAUMA (fl. 1280-1288), Nestorian traveller and diplomatist, was born at Peking about the middle of the 13th century, of Ugur stock. While still young he started on a pilgrimage to Jerusalem, and travelling by way of Tangut, Khotan, Khashgar, Talas in the Syr Daria valley, Khorasan, Maragha and Mosul, arrived at Ani in Armenia. Warnings of the danger of the routes to southern Syria turned him from his purpose; and his friend and fellow-pilgrim, Rabbab Marcos, becoming Nestorian patriarch (as Mar Yaballaha III.) in 1281, suggested Bar Sauma's name to Arghun Khan, sovereign of the Ilkhanate or Mongol-Persian realm, for a European embassy, then contemplated. The purpose of this was to conclude an anti-Moslem alliance, especially against the Mameluks power, with the chief states of Christendom. On this embassy Bar Sauma started in 1285, with Arghun's letters to the Byzantine emperor, the pope and the kings of France and England. In Constantinople he had audience of Andronicus II.; he gives an enthusiastic description of St Sophia. He next travelled to Rome, where he visited St Peter's, and had prolonged negotiations with the cardinals. The papacy being then vacant, a definite reply to his proposals was postponed, and Bar Sauma passed on to Paris, where he had audience of the king of France (Philip the Fair). In Gascony he apparently met the king of England (Edward I.) at a place which seems to be Bordeaux, but of which he speaks as the capital of Angouleme (i.e. Angleterre). On returning to Rome, he was cordially received by the newly elected pontiff Nicolas IV., who gave him communion on Palm Sunday, 1288, allowed him to celebrate his own Eucharist in the capital of Latin Christendom, commissioned him to visit the Christians of the East, and entrusted to him the tiara which he presented to Mar Yaballaha. His narrative is of unique interest as giving a picture of medieval Europe at the close of the Crusading period, painted by a keenly intelligent, broad-minded and statesmanlike observer.

RABBIT, in carpentry and masonry, the name for a rectangular groove or slot cut in the edge of a piece of wood or stone, to which another corresponding piece can be fitted (see JOINERY and MASONRY). The word is an adaptation of the O. Fr. rabat or rabbat, from rabattre, i.e. abattre, beat back, abate, to make a recess, and is thus a doublet of "rabbet" (q.v.), which is now frequently used instead of "rabbet," the joint being also known as a "rabbet joint."

RABI, Hebrew word meaning "my master," "my teacher." It is derived from the adjective rabb (in Aramaic, and frequently also in Hebrew, "great"), which acquired in modern Hebrew the signification of "lord," in relation to servants, or slaves, and of "teacher," "master," in relation to the disciple. The master was addressed by his pupils with the word rabbi ("my teacher"), or rabbanu ("our teacher"). It became customary to speak of Moses as Moshe rabbenu ("our teacher Moses"). Jesus makes it a reproach against the scribes that they cause themselves to be entitled by the people rabbi (rabbî, Matt. xxiii. 7); and He Himself is saluted by the disciples of John as rabi (John i. 36, where the word is explained as equivalent to διδασκαλοῡ). As an honorary title of the scribes, with whose name it was constantly linked, "Rabbi" only came into use during the last decades of the 2nd Temple.

Rabil and Shammal, the contemporaries of Herod, were mentioned without any title. Gamaliel I., the grandson of Hillel, was the first to whose name the appellation Rabban (the same as rabban, and also pronounced as ribbon, cf. haβbōwi, Mark x. 51; John xx. 16) was prefixed. This title, a higher distinction than that of rabi, is in tradition borne only by the descendants of Gamaliel I., the last being Gamaliel III., the son of Jehuda I. (Aboth ii. 2), and by Johanan b. Zaccai, the founder of the school of Jamina (Jabneh). Otherwise all Tannaites (see TANNA), the scholars of the Mishnah period, were distinguished by the title of "rabi." The Jehuda I. mentioned above, the redactor of the Mishnah, was honoured as the "Rabbi" kinav k'eroḥei ("par excellence"), and in the tradition of the houses of learning, if it was necessary to speak of him or to cite his opinions and utterances, he was simply referred to as "Rabbi," without the mention of any name. Scholars who were not definitely ordained—and among these were men of high distinction—were simply mentioned by their names without the Rabbi-title. In the post-Talmudic age the Qaraïtes, who rejected the tradition of the Talmud, designated the Jews who adhered to that tradition as Rabbarites. Similarly the term Rabbins, or Rabbis, is applied to modern Jewish clergy. The plural rabbinim was employed to describe the later Jewish rabbis (so, for example, in the historian Abraham Ibn Daud, 12th century). By "rabbinical literature" is understood the post-Talmudic Jewish literature; in particular, so far as its subject is the literature of the tradition and its contents.

RABBIT, the modern name of the well-known rodent, formerly called (as it still is in English legal phraseology) Coxy,1 a member of the family Leporidae (see RODENTIA). Till recently the rabbit has generally been known scientifically as Lepus cuniculus, but it is now frequently regarded, at least by systematic naturalists, as the representative of a genus by itself, under the name of Oryctolagus cuniculus. Some zoologists, indeed, include in the same genus the South African thick-tailed hare, but by others this is separated as Pronolagus crassicaudatus. From the hare the wild rabbit is distinguished externally by its smaller size, shorter ears and feet, the absence or reduction of the black patch at the tip of the ears, and its greyer colour. The skull is 1 There are no native names either in Teutonic or Celtic languages; such words as German Kaninchen or English cony are from the Latin cuniculus, while the Irish, Welsh and Gaelic are adaptations from English. "Rabbit," which is now the common name in English, was for long confined to the young of the cony, and so the Pronolagus Pseudorutilus, c. 1440, "Rabet, yonge conye, cuniculus." The ultimate source of "rabbit" is itself unknown. The New English Dictionary takes it to be of northern French origin. There is a Walloon rabbit. Skeat suggests a possible connexion with Spanish rabo, tail, rabar, to wag the hind-quarters. The familiar name for toasted cheese, "Welsh rabbit," is merely a joke, and the alteration to "Welsh rare-bit" is due to a failure to see the joke, such as it is. Parallels may be found in "Prairie oyster," the yolk of an egg with vinegar, pepper, &c. added; or "Scotch woodcock," a savoury of buttered eggs on anchovy toast.
very similar to that of the hare, but is smaller and lighter, with a slenderer muzzle and a longer and narrower palate. Besides these characters, the rabbit is separated from the hare by the fact that it brings forth its young naked, blind, and helpless, to compensate for this, it digs a deep burrow in the earth in which they are born and reared. They are born fully clothed with fur, and able to take care of themselves, in the shallow depression or "form" in which they are produced. The weight of the rabbit is from $\frac{2}{3}$ to 3 lb., although wild individuals have been recorded up to more than 5 lb. Its general habits are too well known to need detailed description. It breeds from four to eight times a year, bringing forth each time from three to eight young; its period of gestation is about thirty days, and it is able to bear when six months old. It attains to an age of about seven or eight years.

The rabbit is believed to be a native of the western half of the Mediterranean basin, and still abounds in Spain, Sardinia, southern Italy, Sicily, Greece, Tunis and Algeria; and many of the islands adjoining these countries are overrun with these rodents. Thence it has spread, partly by man's agency, northwards throughout temperate western Europe, increasing rapidly where game is killed; and its extension is still going on, as is shown by the case of Scotland where the 19th century rabbits were little known, while they are now found in all suitable localities up to the extreme north. It has also gained admittance into Ireland, and now abounds there as much as in England. Out of Europe the same extension of range has been going on. In New Zealand and Australia rabbits, introduced either for profit or sport, have increased to such an extent as to form one of the most serious pests that the farmers have to contend against, as the climate and soil suit them perfectly and their natural enemies are too few and too slowly organized to keep them within reasonable bounds. In North America about thirty species and twice as many geographic races (subspecies) are known, and the occurrence of several distinct fossil forms shows that the genus has long been established. The chief variety is the common grey or cottontail (Lepus floridanus). For the "jack-rabbit," see HARE.

The rabbit has been domesticated from an early period. Little doubt exists amongst naturalists that all the varieties of the domestic animal are descended from Oryctolagus cuniculus. The variations which have been perpetuated and intensified by artificial selection are with few exceptions much the same as those of the hare and can be found in any other mammal. For not only has the weight been more than quadrupled in some of the larger breeds, and the structure of the skull and other parts of the skeleton greatly altered, but the proportion of the body has been changed. The rabbit is sleek and compact, and the texture of the fur altered in a remarkable manner. The lop-eared breed is the oldest English variety, and has been cultivated carefully since about 1785, the aim of the breeder being directed to the development of the size of the ears, and with such success that they sometimes measure more than 23 in. from tip to tip and exceed 6 in. in width. This development, which is accompanied by changes in the structure of the skull, depends on breeding the animals in warm damp hutches, without which the best developed parents fail to produce the desired offspring. In colour lop-eared rabbits vary greatly. The Belgian hare is a large breed of a hardy and prolific character, which closely resembles the hare in form and size, and in colour in which the coats were sold as "lopereides" or hybrids, produced by the union of the hare and the rabbit; but the most careful experimenters have failed to obtain any such hybrid, and the naked immature condition in which the young rabbit is born, with the harelip and the highly developed young hare renders it unlikely that hybrids could be produced. Nor does the flesh of the Belgian rabbit resemble that of the hare in colour or flavour. A closely allied variety, though less known, is the Patalaian rabbit, although it has no relation to the country after which it is called.

The Angora rabbit is characterized by the extreme elongation and fineness of the fur, which in good specimens reaches 6 or 7 in. in length; hence comes the name, although it was derived from the Himalayan and the Dutch. The former is white, but the whole of the extremities—viz. the nose, the ears, tail and feet—are black or very dark in colour. This very pretty breed has no connexion with the mountains from which it takes its name, but is a variety produced by careful breeding and selection. Though produced by crossing, it now generally breeds true, colour at times throwing back, however, to the silver greys from which it was derived. The rabbits known as Dutch are small, and valued for the disposition of the colour and markings. The entire body pelage should be absolutely uniform in colour; the body, however, is shorter than the extremities, and black or brown, or both, are acceptable. They are most often used for fur, and the chief variety is the Dalmatian, a large and beautiful breed, differing from its countrymen in the shading of the fur, silver greys having been frequently employed to stock warrens, as they breed true to colour in the open if the ordinary wild rabbits are excluded. Other colours known, as silver fawn and silver brown, are closely related. A breed has been recently introduced. The largest and heaviest of all is the Flemish giant, with iron-grey fur above and white below. Other breeds include the Japanese, with an orange coat, broadly banded on the hind-quarters with black; the pink-eyed and short and thick-haired albino Polish; the Siberian, probably produced by crossing the Himalayan with the Angora; and the black-and-tan and blue-and-tan.

See also HARE, SHOOTING, and COURSING. (W. H. F.; R. L. *)

RABBELE, a general term for a disorderly crowd, apparently connected with the verb "to rabble," to talk or work in a confused manner. Dutch, rabbelen; Ger. dialect. rabbeln; Gr. ῥαββαλεως, to howl. In iron and steel manufacture, a puddling-tool, for stirring the molten metal, is called a "rabbler." This is a different word, adapted from Fr. râble, for râble, Med. Lat. rhabdum, Lat. rhabdulm (ruea, to rake), a fire-shovel or oven rake.

RABBULÀ, a distinguished bishop of the Syrian church early in the 5th century. He was a native of Kenneshrin, a town some few miles south of Aleppo and the seat of a bishopric. His father was a heathen priest, and though his mother was a devoted Christian he continued in pagan belief and practice until some time after his marriage. During a journey to his country estate he was converted to Christianity partly through coming in contact with a case of miraculous healing and partly through the teaching and influence of Eusebius, bishop of Kenneshrin, and Acacius, bishop of Aleppo. With all the energy of his fiery nature he threw himself into the practice of Christian asceticism, sold all his possessions, and separated from his wife and kinspeople. He resided for some time in a monastery, and then passed to a life of greater hardship as a solitary hermit. On the death of Diogenes, bishop of Edessa, in the year 411-412, Rabbûl has been chosen his successor, and at once accepted the position offered him, without any of the customary show of reluctance. As a bishop he was marked by extraordinary energy, by the continued asceticism of his personal life, by his magnificent provision for all the poor and suffering in his diocese, by his care for discipline among the clergy and monks who were under his authority, and latterly by the fierce determination with which he combatted all heresies and especially the growing school of the followers of Nestorius. On one occasion he visited Constantinople and there preached before Theodosius II. (who was then favourable to Nestorius) and after his conversion a sermon in denunciation of Nestorian doctrine, of which a portion survives in the Syriac version. He became the friend of Cyril of Alexandria, with whom he corresponded, and whose treatise De recta fide he translated into Syriac. After a busy episcopal life of twenty-four years he died in August 435, and was immensely lamented by the people of his diocese. His successor was the Nestorian Ibas.

The literary remains of Rabbûl are small in bulk, and are mostly to be found in Overbeck. Perhaps his main importance to the historian of Syriac literature lies in the zeal with which he strove to replace the Diatessaron or Gospel Harmony of Tatian by the edition of the separate Gospels, ordering that a copy of the latter should be placed in every church and should

1 Overbeck, op. cit. pp. 239-244.
2 The version survives in a British Museum MS.; see Wright's Catalogue p. 719.
be read (see Wright’s *Syriac Lit.* p. 9). According to his biographer (Overbeck, p. 172) he himself produced a version (or revision) of the New Testament in Syriac. This may have been, as Wright suggests (Syriac Lit. p. 11), “a first step in the direction of the Philoxenian version.” But there is great probability in F. C. Burkitt’s hypothesis that the product of Rabula’s work, at least as regards the Gospels, is to be found in the current Peshîta text, which “represents the Greek text as read in Antioch about 400 A.D.” and “was prepared by Rabula . . . and published by his authority as a substitute for the Diatessaron.” 1

Rabula seems to have been a man of great force, devotion and self-denial: on the one hand intellectually gifted, and on the other thoroughly consistent in his practice of religion. But his attractiveness is marred, as in the case of many of his contemporaries, by the bitterness of a narrow orthodoxy.

(N. M.)

**RABELAIS, FRANÇOIS** (c. 1490–1553), French humorist, was born at Chinon on the Vienne in the province of Touraine. The date of his birth is wholly uncertain; it has been put by tradition, and by authorities long called to his death, as 1483, 1490, and 1495. There is nothing in the positive facts of his life which would not suit tolerably well with any of these dates; most 17th-century authorities give the earliest; and this also accords best with the age of the eldest of the Du Bellay brothers, with whom Rabula was (perhaps) at school. In favour of the latest it is urged that, if Rabula was born in 1483, he must have been forty-seven when he entered at Montpellier, and proportionately and unexpectedly old at other known periods of his life. In favour of the middle date, which has, as far as recent authorities are concerned, the weight of consent in its favour, the testimony of Guy Patin (1601–1672), a witness of some merit and not too far removed in point of time, is invoked. The only contribution which need be made here to the controversy is to point out that if Rabula was born in 1483 he must have been an old man when he died, and that scarcely even tradition speaks of him as such.

With regard to his birth, parentage, youth, and education everything depends upon this tradition, and it is not until he was accorded to one extreme hypothesis thirty-six, according to the other extreme twenty-four, that we have solid testimony respecting him. In the year 1519, on the 5th of April, the François Rabula of history emerges. The monks of Fontenay le Comte bought some property (half an inn in the town), and among their signatures to the deed of purchase is that of François Rabula. Before this all is cloudland. It is said that he had four brothers and no sisters, that his father had a country property called La Devinière, and was either an apothecary or a tavern-keeper. Half a century after his death De Thou mentions that the house in which he was born had become a tavern and then a tennis-court. It still stands at the corner of a street called the Rue de la Lamproie, and the tradition may be correct. An indistinct allusion of his own has been taken to mean that he was tounsed in childhood at seven or nine years old; and tradition says that he was sent to the convent of Seuilly. From Seuilly at an unknown date tradition takes him either to the university of Angers or to the convent school of La Baumette or La Basmette, founded by good King René in the neighbourhood of the Angevin capital. Here he is supposed to have been at school with the brothers Du Bellay, with Geoffroy d’Estissac and others. The next stage in this (so far as evidence goes, purely imaginary) career is the monastery of Fontenay le Comte, where, as has been seen, he is certainly found in 1519 holding a position sufficiently senior to sign deeds for the community, where he, probably in 1511, took priest’s orders, and where he also pursued, again certainly, the study of letters, and especially Greek and Latin, at the convent. By 1518, or at the latest by 1519, he becomes historically visible. The next certain intelligence which we have of Rabula is somewhat more directly biographical. The letters of the well-known Greek scholar Budaeus, two of which are addressed to Rabula himself and several more to his friend and fellow-monk Pierre Amy, together with some notices by André Tiraqueau, a learned jurist, to whom Rabula rather than his own learning has secured immortality, show beyond doubt what manner of life the future author of *Gargantua* led in his convent. The letters of Budaeus show that an attempt was made by the heads of the convent or the order to check the studious ardour of these Franciscans; but it failed, and there is no positive evidence of anything like actual persecution, the phrases in the letters of Budaeus being merely the usual exaggerated Ciceronianism of the Renaissance. Some books and papers were seized as suspicious, then given back as innocent; but Rabula was in all probability disgusted with the cloister—indeed his great work shows this beyond doubt. In 1524, the year of the publication of Tiraqueau’s book cited, his friend Geoffroy d’Estissac procured from Clement VII the induct, licensing a change of order and of abode for Rabula. From a Franciscan he became a Benedictine, and from Fontenay he moved to Maillezeais, of which Geoffroy d’Estissac was bishop. But even this learned and hospitable retreat did not apparently satisfy Rabula. In or before 1530 he left Maillezeais, abandoned his Benedictine garb for that of a secular priest, and, as he himself puts it in his subsequent *Supplizatio pro Apostasia* to Pope Paul III, “pro seculum diu vagatus fui.” For a time the Du Bellays provided him with an abode near their own château of Langle. He is met at Montpellier in the year just mentioned. He entered the faculty of medicine there on the 16th of September and became bachelor on the 1st of November, a remarkably short interval, which shows what was thought of his acquirements. Early in 1531 he lectured publicly on Galen and Hippocrates, while his more serious pursuits seem to have been channeled by acting in a *morale comédie*, then a very frequent university amusement. Visits to the Îles d’Hères, and the composition of a fish sauce in imitation of the ancient *garum*, which he sent to his friend Étienne Dolet, are associated, not very certainly, with his stay at Montpellier, which, lasting rather more than a year at first, was renewed at intervals for several years.

In 1532, however, he had moved from Montpellier to Lyons. Here he plunged into manifold work, literary and professional. He was appointed before the beginning of November physician to the Hôtel Dieu, with a salary of forty livres per annum, and lectured on anatomy with demonstrations from the human subject. He edited for Sebastian Gryphius, in the single year 1532, the medical *Epistles* of Giovanni Manardi, the *Aphorisms* of Hippocrates, with the *Ars Parsa* of Galen, and an edition of two supposed Latin documents, which, however, happened unluckily to be forgeries.

At this time Lyons was the centre and to a great extent the headquarters of an unusually enlightened society, and indirectly it is clear that Rabula became intimate with this society. A manuscript distich, which was found in the Toulouse library, deals with the death of an infant named Théodule, whose country was Lyons and his father Rabula, but we know nothing more about the matter. What makes the Lyons sojourn of the greatest real importance is that at this time probably appeared the beginnings of the work which was to make Rabula immortal. It is necessary to say “probably,” because the strange uncertainty which rests on so much of his life and writings exists here also. There is no doubt that both *Gargantua* and *Pantagruel* were popular names of giants in the Middle Ages, though, curiously enough, the actual names of the giants in the French *Gargantua* and *Pantagruel* before Rabula’s time has been traced. In 1526, however, Charles de Borendeg, in a satiric work of no great merit, entitled *la Légende de Pierre Faisil*, has the name Gargantua with an allusion, and in 1532 (if not earlier) there appeared at Lyons *Les Grands et insénéables chroniques du grand et énorme géant Gargantua*. This is a short book on the plan of the later burlesques and romances of the Round Table. Arthur and Merlin appear with Grantgoser, as he is here spelt, Ganelle (Garamelle), Gargantua himself,
and the terrible mare. But there is no trace of the action or other characters of Gargantua that was to be, nor is the manner of the piece in the least worthy of Rabelais. No one supposes that he wrote it, though it has been supposed that he edited it and that in reality it is older than 1532, and may be the direct subject of Bordigné’s allusion six years earlier. What does, however, seem probable is that the first book of Pantagruel (the second of the whole work) was composed with a definite view to this chap book and not to the existing first book of Gargantua, which was written afterwards, when Rabelais discovered the popularity of his work and felt that it ought to have some worthier starting-point than the Grandes chroniques. The earliest known and dated edition of Pantagruel is of 1533, of Gargantua 1535, though this would not be of itself conclusive, especially as we actually possess editions of both which, though undated, seem to be earlier. But the definite description of Gargantua in the title as “Père de Pantagruel,” the omission of the words “second livre” in the title of the first book of Pantagruel while the second and third are duly entitled “tiers” and “quart,” the remarkable fact that one of the most important personages, Friar John, is absent from book ii., the first of Pantagruel, though he appears in book i. (Gargantua), and many other proofs show the order of publication clearly enough. There is also in existence a letter of Calvin, dated 1533, in which he speaks of Pantagruel, but not of Gargantua, as having been condemned as an obscene book. Besides this, 1533 saw the publication of an almanac, the first of a long series which exists only in titles and fragments, and of the amusing Prognostication Pantagrueline (still, if it is observed, Pantagrueline, not Gargantuine). Both this and Pantagruel itself were published under the anagrammatic pseudonym of “Alcofridas Nasiër,” shortened to the first word only in the case of the Prognostication.

This busy and interesting period of Rabelais’s life was brought to a close apparently by his introduction or reintroduction to Jean du Bellay, who, in October 1533, passing through Lyons on an embassy to Rome, engaged Rabelais as physician. The visit did not last very long, but it left literary results in an edition of a description of Rome by Marliani, which Rabelais published in September 1534. It is also thought that the first edition of Gargantua may have appeared this year.

In the spring of 1535 the authorities of the Lyons hospital, considering that Rabelais had twice absented himself without leave, elected Pierre de Castel in his room; but the documents which exist do not seem to infer that any blame was thought due to him, and the appointment of his successor was once definitely postponed in case he should return. At the end of 1535 Rabelais once more accompanied Jean du Bellay, now a cardinal, to Rome and stayed there till April in the next year. This stay furnishes some biographical documents of importance in the shape of letters to Geoffroy d’Estissac, of the already-mentioned Supplicatio pro Apostasia, and of the bull of absolution which was the reply to it. This bull not only freed Rabelais from ecclesiastical censure, but gave him the right to return to the order of St Benedict when he chose, and to preach and teach everywhere. This bull was a confirmation of the canon of St Maur. In 1537 he took his doctor’s degree at Montpellier, lectured on the Greek text of Hippocrates, and next year made a public anatomical demonstration. During these two years he seems to have resided either at Montpellier or at Lyons. But in 1539 he entered the service of Guillaume du Bellay-Langey, elder brother of Jean, and would appear to have been with him (he was governor of Piedmont) till his death on 9th January 1543. Rabelais wrote a panegyric memoir of Guillaume, which is lost, and the year before saw the publication of an edition of Gargantua and Pantagruel, book i., together (both had been repeatedly reprinted separately), in which some dangerous expressions were cut away. Nothing at all is known of his life, whereabouts, or occupations till the publication of the third book, which appeared in 1546, “avec privilège du roi,” which had been given in September 1545.

Up to this time Rabelais, despite the condemnation of the Sorbonne referred to above, had experienced nothing like persecution or difficulty. Even the spiteful or treacherous act of Dolet, who in 1542 reprinted the earlier form of the books which Rabelais had just slightly modified, seems to have done him no harm. But the storm of persecution which surrounded the end of the reign of Francis I. was fatal to Dolet himself and to Des Périers, while it exiled and virtually killed Marot, threatened him. There is no positive evidence of any measures taken or threatened against him; but it is certain that he passed nearly the whole of 1546 and part of 1547 at Metz in Lorraine as physician to the town at the salary of 120 livres, and Sturm speaks of him as having been “cast out of France by the times” (with the exclamation φησι τῶρ χρώμα) in a contemporary letter, and says that he himself in another letter gives a doleful account of his pecuniary affairs and asks for assistance. At Francis’s death on 31st March 1547 Du Bellay went to Rome, and at some time not certain Rabelais joined him. He was certainly there in February 1549, when he dates from Du Bellay’s palace a little account of the festivals given at time to celebrate the birth of the second son of Henry II. and Catherine de’ Medici. This account, the Sciomachie as it is called, is extant. In the same year a monk of Fontevraud, Gabriel du Puits-Herbault, made in a book called Theolimus the first of the many attacks on Rabelais. It is, however, as vague as it is violent, and it does not seem to have had any effect. Rabelais had indeed again made for himself protectors whom no clerical or Sorbonist jealousy could touch. The Sciomachie was written to the cardinal of Guise, whose family were all-powerful at court, and Rabelais dedicated his next book to Odet de Chatillon, afterwards cardinal, a man of great influence. Thus Rabelais was able to return to France, and in 1550 was presented to the livings of Meudon and St Christophe de Jambet. It may, however, surprise those who have been accustomed to hear him spoken of as “curé de Meudon,” and who have read lives of him founded on legend, to find that there is very little ground for believing that he ever officiated or resided there. He certainly held the living but two years, resigning it in January 1552 along with his other benefice, and it is noteworthy that at the episcopal visitation of 1551 he was not present. To this supposed residence at Meudon and to the previous stay at Rome, however, are attached two of the most mischievous items of the legend, though fortunately two of the most easily refutable. It is said that Rabelais met and quarrelled with Joachim du Bellay the poet at Rome, and with Ronsard at Meudon and elsewhere, that this caused a breach between him and the Pléiade, that he satirized its classicizing tendencies in the episode of the Limousin scholar, and that Ronsard after his death avenged himself by a libellous epitaph. The facts are these. Nothing is heard of the quarrel with Du Bellay or of any meeting with him, nothing of the meetings and bickerings with Ronsard, till 1567, when Bernier tells the story without any authority. The supposed allusions to the Pléiade date from a time when Rabelais was a small boy, and are mainly borrowed from an earlier writer still, Geoffroy Tory. Whether the Pléiade read Rabelais impartially, is not libellous at all, but simply takes up the vein of the opening scenes of Gargantua in reference to Gargantua’s author. There is indeed no reason to suppose that either Ronsard or Du Bellay was a fervent admirer of Rabelais, for they belonged to a very different literary school; but there is absolutely no evidence of any enmity between them, and Du Bellay actually refers to Rabelais with admiration.

Some chapters of Rabelais’s fourth book had been published in 1548, but the whole did not appear till 1552. The Sorbonne censured it and the parliament suspended the sale, taking advantage of the king’s absence from Paris. But it was soon relieved of the suspension. He died, it is said, on the 9th of April 1553, but actual history is quite silent save on the point that he was not alive in May of the same year, and the legends about his deathbed utterances—“La farce est jouée,” “Je vais chercher un grand peut-être,” &c.—are altogether
apocryphal. The same may be said of the numerous silly stories told of his life, such as that of his procuring a free passe to Paris by inscribing packets “Poison for the king,” and so forth.

Ten years after the publication of the fourth book and nine after the supposed date of the author’s death there appeared at Lyons sixteen chapters entitled *Ille sonnante par maistre Francois Rabelais*, and two years later the entire fifth book was printed as such. In 1567 it took place with the others, and has ever since appeared with them. But from the beginning of the 17th century there have never been wanting disbelievers in its authenticity. The controversy is one of some intricacy, but as it is also one of capital importance in literary history the heads of it at least must be given here.

The opponents of the book rely (1) on the testimony of a certain Louis Guyon, who in 1604 declared that the fifth book was made long after Rabelais’s death by an author whom he knew, and who was not a doctor, and on the assertion of the bibliographer Du Verdier, about the same time, that Du Verdier himself, writing an “écolier de Valenciennes’” (2) on the fact that the antennastic and even anti-Catholic polemic is much more accentuated in it; (3) on the arguments that parts are apparently replicas or rough drafts of passages already appearing in the four earlier books; and (4) that some allusions are manifestly posterior to even the furthest date which can be assigned for the reputed author’s decease. On the other hand, it is urged that, though Guyon and Du Verdier were in a sense contemporaries, they wrote long after the events, and that the testimony of the former is vitiated, not merely by its extreme vagueness, but by the fact that it occurs in a *plaidoyer*, tending to exculpate physicians from the charge of unorthodoxy; that Du Verdier in another place assigns the *Pantagrueline Prognostication* to this same unknown student of Valence, and had therefore probably confused and hearsay notions on the subject; that the rasher and fiercer tone, as well as the apparent repetitions, are sufficiently accounted for on the supposition that Rabelais never finally revised the book, which indeed dates show that he could not have done so, as the fourth was not finally settled till just before his death; and that it is perfectly probable, and indeed almost certain, that it was prepared from his papers by another hand, which is responsible for the anachronous allusions above referred to. But the strongest argument, and one which has never been attacked by authorities really competent to judge, is that the “griffe de l’aigle” is on the book, and that no known author of the time except Rabelais was capable of writing the passage about the *Chats fourrés*, the better part of the history of Queen Whims (La Quinte) and her court, and the conclusion giving the Oracle of the Bottle. To this argument we believe that the more competent a critic is, both by general faculty of appreciation and by acquaintance with contemporary French literature, the more positive will be the assent that he yields. The reader must, however, be on his guard against confusing the authenticity of the fifth book generally with that of any particular passage in it. Quite recently it was announced that an edition of 1540 had turned up in Germany; but the investigations of M. R. Stein, an *Rabelais apocryphe* (1901), repeated and confirmed by M. A. Lefranc in the *Revue des études Rabelaisiennes* (1905), disposed of the matter.

The substance of the apocryphal document is quite different from our fifth book.

Gargantua and Pantagruel, notwithstanding their high literary standing and the frequency with which certain passages from them are cited, are, owing partly to their archaisms of language and partly to the extreme licence which their author has allowed himself, so little read that no notice of their decline seems worth while taking of their present state. The first book, *Gargantua*, describes the birth of that hero (a giant and the son of gigantic parents), whose nativity is ushered in by the account of a tremendous feast. In this the burlesque exaggeration of the pleasures of eating and drinking, which is one of the chief exterior notes of the whole work, is pushed to an extreme—an extreme which has attracted natural but perhaps undue attention. Very early, however, the author becomes serious in contrasting the early education of his hero—a satire on the degraded schools of the middle ages—with its subsequent and reformed stage, in the account of which all the best and noblest ideas of the humanist Renaissance in reference to pedagogy are put with exceptional force. Gargantua and his father go to Paris, and there, with added licence, he is educated, owing to a war between his father, Grandgousier, and the neighbouring king, Picrochole. This war is described at great length, the chief hero of it being the monk, Friar John, a very unclerical Pantagruel, whose princely conduct, diehardness of spirit, and peace and peace, Gargantua establishes the abbey of Thelama in another of Rabelais’s most elaborate literary passages, where all the points most ominous to him in monastic life are indicated that the punishment of asceticism, the extravagance of the contemplative life, and the heterodoxy of the Roman Church. The second book, which introduces the principal hero of the whole, Pantagruel, Gargantua’s son, is, on any other hypothesis but that already suggested of its prior composition, very difficult to explain, but it is this book which is by far the most amusing, and through something like a second edition (really a first) of the educational adventures of his father. Like him, he goes to Paris, and there meets with Panurge, the principal triumph of Rabelaisian characteristic, and the most original of all as anything fule of the book. Panurge has almost all intellectual accomplishments, but is totally devoid of morality: he is a coward, a drunkard, a lecher, a spiteful trickster, a spendthrift, but all the while infinitely amusing. This book, like otherwise, this singular romance is diversified by, or to speak more properly, it is the vehicle of the most bewildering abundance of digression, burlesque amplification, covert satire on things political, social and religious, miscellaneous erudition and devotional interpolations and dreams, and wit. This work yields the single word “Trinq,” which the attendant priestess declares to be the most gracious and intelligible she has ever heard from him. Panurge takes this as a sanction of his marriage, and the book ends accordingly. This book, on the whole, is an elaborate croy of the “verb pantagruelique,” which appears to be, if it is anything, hemp. Only two probable explanations of this have been offered, the one seeing in it an anticipation of Joseph de Maistre’s glorification of the executioner, the other a croy of work, hemp being on the whole the most serviceable of vegetable products for that purpose. The fourth and fifth books are entirely taken up with a description of the voyage. Many singular places, with the descriptions of the French writers, offering obvious satire on human institutions, others, except by the most far-fetched explanations, resolvable into nothing but sheer extravaganzas. At last the Land of Lanterns, borrowed from Lubin in another of the Bottle is consulted. It yields the word “Trinq,” which the attendant priestess declares to be the most gracious and intelligible she has ever heard from it. Panurge takes this as a sanction of his marriage, and the book ends accordingly. RABELAIS

and Esangarg, have generally committed the error of torturing themselves and their author to find individual explanations of personages and events. The extravagance of the last-named commentator takes the form of seeing elaborate allegories; that of some others devotes itself chiefly to identifying the characters of the romance with more or less famous historical persons. But the first blunder, that of forming a general hypothetical conception of Rabelais and then adjusting interpretation of the work to it, is more or less a general protest against any attempt to explain supernaturally the riddle of the earth. According to a third class, the most distinguished representative of which was M. Lucron, the Rabelaisian legend does not so much err in essence as it invents in fact. Rabelais is the incarnation of the "esprit Gauvain," a jovial, careless soul, not destitute of common sense or even acute intellectual power, but first of all a good fellow, rather than a wise man. His was a good-natured life, like a good-natured undergraduate. Of all these views it may be said that those who held them are obliged to shut their eyes to many things in the book and to see in it many which are not there. This is perhaps the case with most of the above-mentioned; but it is impossible to think that any unbiased judge reading Rabelais can hold the grave-philosopher view or the reckless-goodfellow view without modifications and allowances which practically deprive the former of all its value. It has been happily put, identify Rabelais with Pantagruel, strive in vain, intellectuals and morally respectable, to account for the vast ocean of pure or impure laughter and folly which surrounds the few solid islets of sense and reason and devotion. Those who in the last resort, in the Rabelaisian universe, are the object of the education scheme, the solemn apparition of Gargantua among the farcical and fantastic variations on Panurge's wedding, and many other passages; while, on the other hand, those who insist on a fishy, dirty, dirty book were left with a live one, the real Rabelais, the real and genuine Pantagruel, with his "dirty old blackguard!"

He has had evidence of his long and steady sojourn in the cloister (a sojourn which was certainly not less than five-and-twenty years), and who has not read the first twopenny halfpenny hardbacks through the stubbornness rests not on legend but on documentary evidence) acquired a vast stock of learning. He was, it is clear, thoroughly penetrated with the instincts, the hopes, and the ideas of the Renais­sance, which was, in England and in Germany—a form, that is to say, not merely by the greatness of aspirations for social and political improvement, and above all for a joyous, varied, and non-ascetic life. He had thoroughly convinced himself of the abuses to which monachism lent itself. As he had no fear of any cramping or stifling purpose that the great in loco which frequently goes with the love of books. It is in the highest degree improbable that in beginning his great work he had any definite purpose or intention. The habit of burlesquing the formes d'ant GREEN was new to one, and the form lent itself alike to the two literary exercises to which he was most devoted—apt and quaint citation from and variation on the classics and satirical criticism of the life he saw around him. The immense range which the subject allowed may have been due to the difficulty of expressing it by degrees (the genuineness of the fifth book, at any rate in substance, is here assumed) the possibility of giving the whole something like a consistent form and a regular conclusion presented itself to him as an easy task, and he formed an ideal of using it in its place as a sound and satirical allusion, and he availed himself of that licence in the widest sense. Here and there persons are glanced at, while the whole scenery of his birthplace and its neighbourhood is curiously worked in; this, however, is the centre is typical rather than individual, and it is on the whole a rather crude attempt to give a general view of both Rabelais and the world. To this must be added the crying abuses of their church, and both at the time and since have been disliked and attacked by the more impudent partisans of that church. But Rabelais, in his own way, held off from the world's day; and the habit of burlesquing and of discrediting, if not of directly anti-Chistian thinking, has always been more common and has recently found much favour. It is, however, remarkable that those who hold this opinion never give voice to it, at least not at review of the chapter, and verse cannot be given. The sayings attributed to Rabelais which colour the idea (such as the famous "Je vais chercher un grand peut-être," said to have been uttered on his death-bed) as has been said, purely apocryphal. In the book itself nothing
of the kind is to be found. Perhaps the nearest approach to it is a jest at the Sorbonne couched in the Pauline phrase about "the evidence of things not seen," which the author removed from the later editions. But irreverences of this kind, as well as the frequent burlesque and later hypothesis) written tender say as works most computed de which has been, have since been, and are common in writers whose orthodoxy is unquestioned; and it must be remembered that the later Middle Age, which in many respects Rabelais represents almost as the kind of the kind of the kind of questioning faith, singularly reckless, and, to our fancy, irrelevant in its use of the sacred words and images, which were to it the most familiar of all images and words. On the other hand, there are many passages in the description of Gargantua's education, in the sketch of the abbey of Théclema, in several passages relating to Pantagruel, expressions which either signify a sincere and unfeigned piety of a simple kind or else are inventions of the author's fancy, as the doctrine of the unorthodoxy, which is so many to be found from the Renaissance to the end of the 18th century, obvious flags of truce to cover attacks—mere bowings in the house of Rimmon to prevent evil consequences. There is also, however, a kind of thesis to prove would dream of taking them in a non-natural sense. It is not, indeed, to be contended that Rabelais was a man with whom religion was in detail a constant thought, that he had a very tender, a very sacred, a very personal religion. His religious sentiment was not evangelical or mystical, any more than it was ascetic or ceremonial or dogmatic. As regards one of the accepted doctrines of his own church, the excellence of the celibate life, there is no question but that a man in a story of a world was a strong dissident; but the evidence that, as a Christian, he was unorthodox, that he was even a heretical or latitudinarian thinker in regard to those doctrines which the various Christian churches of the Middle Ages have always held to be essential, is not so existent. The counter-testimony is, indeed, not very strong, and still less detailed. But that is not the point. It is sufficient to say that there is absolutely nothing within the covers of Rabelais's works which can be termed an orthodox religious sentiment. It is as sufficient by Christendom at large, leaving out of the question those points of doctrine and practice on which Christians differ. Beyond this no wise man will go, and short of it hardly any unprejudiced man will stop.

BIBLIOGRAPHY.—The dates of the original editions of Rabelais's works have been given where possible already. The earlier books were repeatedly reissued during the author's life, and always with some correction. What may be called the first complete edition appears in 1552 at Lyons, published by G. de Moutaye. It is reported that not less than sixty editions were printed before the close of the 16th century. A very considerable number, however, eluded before the works were, properly speaking, edited. Huët devoted much of his time to the study of this subject. His contribution to the first edition which calls for notice, except in a complete bibliography, is that of Le Duchat (Amsterdam, 1731). Le Duchat was a very careful student, and on the whole a very efficient editor, being perhaps, indeed, the ground-study of modern scholarship. The first edition is one of the handsomest, most sober, critical, and accomplished. But at that time the knowledge of the period was scarcely far enough advanced. The next important was the edition of Le Duc and Rabener (1825), in which year appeared the most elaborate edition of his works, published, of Esangart and Johanneau (9 vols.), including for the first time the Songs Drolatiques, a spacious but early and not uninteresting collection of miscellaneous verse. Among the most valuable early editions is that of the Collection Didot by Burgaud des Marais and Rathery (1857 and later); the Bibliothèque Élégivincée edition of M.M. Lacour and A. de Montaiglon; the Nouvelle Collection Jannet (seven volumes, 1867-73); completed by M. de Liscow (1874), and lastly, the edition of M. Marty-Laveaux in the Collection Lemerre (1868-1903), the handsomest, the most accurate, and the most complete, in the scholarly sense, yet published. Commentaries on Rabelais's works have been written by almost every one of the work of Jean Bernier, Jaugment et nouvelles observations sur les eaux... de M. François Rabelais (1597), onwards. Of those of the last half-century the best are, besides essays in the works of most of the moderns, notably those of Noël, of Rabelais (1868); Jean Fleury (1876); Paul Stapler (the best of all) (1889); and G. Vallat (1899). Separate points have been treated importantly by A. Heuland, Dernières années de Rabelais (1884), and others; which the Révue des études Rabelaisiennes (1893) contains valuable studies, especially those of M. Abel Lefranc.

Rabelais was very early popular in England. There are possible allusions to him in Shakespeare, and the current clerical notion of him is very unjustly adopted by Marston in the words "wicked Rabelais"; but Bacon described him better as the great jester of France, and a Scot, Sir Thomas Urquhart, translated the earlier books of Gargantua and Pantagruel. The English translation of 1833 was adapted from the French, and is Rabelais, O., or his fellow countryman, the French, T. Rabet, finished it with an extensive commentary. It has been frequently reprinted. A new translation by W. F. Smith appeared in 1893. Criticism of the English was abundant; but it is not Coleridge being the most important, while the constant evidence of his influence in Southey's Doctor is also noteworthy. But he was most largely treated as a whole before Sir Walter Besant's book on Rabelais (1871). The book which followed up with Readings from Rabelais (1883). Somewhat elaborate treatments of him in connexion with contemporaneous literature will be found in George Saintsbury's The Earlier German Anonymous Prose (1893) and in A. Tille's Literature of the French Renaissance (1904).
may be credited, he had not learnt even Latin. But in middle life he inherited some property, and he was thus able to devote himself to the practice of poetry, in which he was the faithful, and perhaps the most distinguished, disciple of Malherbe. He had known Malherbe when he was a page at the court of Henry IV., and had early contributed to the fashionable albums of the day. In 1625 he published his most important work, *Bergeries*, a dramatic pastoral in five acts, a part of which, entitled *Arithencie*, was played in 1618. Racan was also the author of Sept psaumes (1631), Odes sacrés tirées des psaumes de David (1651), *Dernières œuvres et poésies chrétiennes* (1660), in all of which he was hampered by his inability to read the sacred writings except in other French paraphrases. He was one of the original members of the French Academy. He died in February 1670.

His *Œuvres complètes* were edited by Tenant de Latour in 1857, and the edition includes a biographical notice. See Sainte-Beuve, *Couvertures du lundi*.

**Racconigi**, a town of Piedmont, Italy, in the province of Cuneo, 24 m. S. of Turin, and 31 m. N. of Cuneo by rail, 837 ft. above sea-level. Pop. (1901) 7364 (town); 9077 (commune). It has a royal château built in 1570, with a large park laid out in 1753 by the French gardener Molard from designs by Le Notre, and enlarged in 1835. Since 1901 it has been the summer residence of the king of Italy.

**Raccoon (or Raccoon)**, a name borne by the typical representative of a group of American arboreal placental mammals belonging to the order Carnivora (q.v.) and the family Procyonidae. The word is a corruption of the North-American Indian "arrakhkune" or "arachkone." The Fr. *raton* or *raton laveur*, Ger. *Waschbär*, and other European names are derived from a curious habit the raccoon has of dipping or washing its food in water before eating it. The typical raccoon (*Procyon lotor*) is a thickly built animal about the size of a badger, with a coat of long coarse greyish-brown hairs, short ears, and a bushy black-and-white ringed tail. Its range extends over the whole of the United States, and stretches on the west northwards to Alaska and southwards well into Central America, where it attains its maximum size. The following notes on the habits of the raccoon are from Dr. C. Hart Merriam's *The Mammals of the Adirondacks*—

"Raccoons are omnivorous beasts and feed upon mice, small birds, birds' eggs, turtles and their eggs, frogs, fish, crayfish, molluscs, insects, nuts, fruits, maize and sometimes poultry. Excepting along the banks and flying-squirrels, they are the most strictly nocturnal of all our mammals, and yet I have several times seen them abroad on cloudy days. They haunt the banks of ponds and streams, and find much of their food in these places, such as crayfish, mussels and fish, although they are unable to dive and pursue the latter under water, like the otter and mink. They are good swimmers and do not hesitate to cross rivers that lie in their path... The raccoon hibernates during the severest part of the winter, retiring to its nest rather early, and appearing again in February or March, according to the earliness or lateness of the season. It makes its home high up in the hollow of some large tree, preferring a dead limb to the trunk itself. It does little in the way of constructing a nest, and from four to six young are commonly born at a time, generally early in April in this region. The young remain with the mother about a year."

The South-American species, *P. cancrivorus*, the crab-eating raccoon, is very similar to *P. lotor*, but differs by its shorter fur, larger size, proportionally more powerful teeth and other minor characters. It extends over the whole of South America, as far south as the Rio Negro, and is common in all suitable localities. Its habits are similar to those of the North-American species.

**Raccoon-DOG** (*Nectereutes procyonoides*), a small wild dog, with sharp-pointed muzzle, short rounded ears, bushy tail and long fur, found in China, Japan and Amurland. The total length is about 32 in., of which the tail measures 4 in. The prevailing hues are black and dusky yellow, the distribution of which varies in different individuals. In habit these dogs are chiefly nocturnal; and they are said to hibernate. In winter they feed on fish, and in summer on mice, forming small packs to hunt their prey.

**Race**, an homonymous word of which the principal meanings are (1) a trial or contest of speed; (2) a tribe, breed, a group of individuals descended from a common ancestor. In the first case the word is an adaptation of O.Nor. *rás*, a cognate form in OE. being *ras*, rush, onset; while the O.E. descendant *rese* was frequently used in medieval poetry. The particular use of the word for a swift current of water running through a narrow channel, e.g. the Race of Alderney, and for the water conducted in an artificial channel to a point where its power is to be used, as in "mill-race," may be due to the O.Fr. *ras* or *race*, probably of Breton origin. The second word, an ethical or national stock, comes from Fr. *race*, adapted from Ital. *rasa*, cf. Span. *raza*. It has been referred to an O.H.G. *reiza*, line, mark, cognate with Eng. "write," i.e. the line marking descent.

**Rachel** (1821-1858), French actress, whose real name was Elizabeth Félix, the daughter of poor Jew peddlars, was born on the 25th of February 1821, at Mumpf, in the canton of Aarau, Switzerland. At Reims she and her elder sister, Sophia, afterwards known as Sarah, joined a troupe of Italian children who made their living by singing in the cafés; Sarah singing and Elizabeth, then only four years of age, collecting the coppers. In 1830 they came to Paris, where they sang in the streets; Rachel giving such patriotic songs as the *Parisienne* and the *Marseillaise* with a rude but precocious energy which evoked special admiration and an abundant shower of coppers. Étienne Choron, a famous teacher of singing, was so impressed with the talents of the two sisters that he undertook to give them gratuitous instruction, and after his death in 1833 they were received into the Conservatoire. Rachel made her first appearance at the Gymnase in Paul Duport's *La Vendéenne* on the 4th of April 1837, with only mediocre success. But on the 12th of June in the following year she succeeded, after great difficulty, in making a début at the Théâtre Français, as Camille in Cornelle's *Horace*, where her remarkable genius at once received general recognition. In the same year she played Roxane in the *Comédie* *Racine's Bajazet*, winning complete triumph. It was in *Racine's Phèdre*, which she first played on the 21st of January 1843, that her peculiar gifts were most strikingly manifested. Her range of characters was limited, but within it she was unsurpassable. She excelled particularly in the impersonation of evil or malignant passion, her presentation of which there was a majesty and dignity which fascinated while it repelled. By careful training her voice, originally hard and harsh, had become flexible and melodious, and its low and muffled notes under the influence of passion possessed a thrilling and penetrative quality that was irresistible. In plays by contemporary authors she created the characters of Judith and Cleopatra in the tragedies of Madame de Girardin, but perhaps her most successful appearance was in 1849 in Scribe and Legouvé's *Adrienne Lecouvreur*, which was written for her. In 1841 and in 1842 she visited London, where her interpretations of Cornellie...
and Racine were the sensation of the season. In 1855 she made a
tour in the United States with comparatively small success, but
this was after her powers, through continued ill-health, had
begun to deteriorate. She died of consumption at Cannet, near
Nice, on the 4th of January 1858, and was buried in the Jewish
part of the cemetery of Père Lachaise in Paris. Rachel's third
sister was Lin Félix (q.v.).

Kennard, Rachel (Boston, 1888); and A. de Faucigny-Lucinge,
Rachel et son temps (1910).

RACINE, JEAN (1639-1699), French tragic dramatist, was
born at La Ferté Milon in the old duchy of Valois on an uncertain
date in December 1639. He was certainly christened on the
22nd, and the ceremony was at that time often, though not
invariably, performed on the day of birth. Racine belonged to
a family of the upper bourgeoisie, which had indeed been technically
ennobled some generations earlier, and bore the punning
arms of a rat and a swan (rat, cygne). The poet himself subse-
sequently dropped the rat. His family were connected with
others of the same or a slightly higher station in La Ferté and
its neighbourhood—the Desmoulins, the Scouins, and the Vitarts,
all of whom were of Racine's life. His mother was Jeanne
Scouin. His father, of the same name as himself, was only
four-and-twenty at the time of the poet's birth. He seems to
have been a solicitor (procureur) by profession, and held, as his
father, the grandfathers of the dramatist, had done, the office of
contrôleur au grenier à sel. Racine was the eldest child. Little
more than a year afterwards his sister Marie was born and his
mother died. Jean Racine the elder married again, but three
months later he himself died, and the stepmother is never heard
of in connexion with the poet or his sister. They were left
without any provision, but their grandparents, Jean Racine
the eldest and Marie Desmoulins, were still living, and took
to charge of them. These grandparents had a daughter, Agnes,
who figures in Racine's history. She was a nun and later abbess
of Port Royal under the style of Mère de Sainte Thérèse, and
the whole family had strong Jansenist leanings. Jean Racine
the eldest died in 1649, and the poet was sent to the Collège
de Beauvais. This (which was the grammar-school of the town
of that name, and not the famous Collège de Beauvais at Paris)
was intimately connected with Port Royal, and to this place
Racine was transferred in November 1655. His special masters
there were Nicole and Le Maître. The latter, in an extant
letter written to his pupil, speaks of himself as “votre papa.”
It is evident from documents that he was a very diligent student
both at Beauvais and Port Royal. He wrote verse both in
Latin and French, and his Port Royal odes, which it has been
the fashion with the more fanatical admirers of his later poetry
to ridicule, are far from despicable.

Racine stayed at Port Royal for three years, and left it, when
nearly nineteen, in October 1658. He was then entered at the
Collège d'Harcourt and boarded with his second cousin, Nicolas
Vitart, steward of the duke of Luynes. Later, if not at first,
he lived in the Hôtel de Luynes itself. It is to be observed
that his Jansenist surroundings continued with him here, for the
duke of Luynes was a severe Port Royalist. It is, however,
evident that Racine, whatever others may think of us, we have it,
began in 1660 and is for some years very abundant and interesting,
that he was not at all of an austere disposition at this time.
Occasionally the liveliness of the letters passes the bounds of strict decency, though there is nothing very shocking
in them, and those to Madame (or, as the habit of the time called
her, Mademoiselle) Vitart are free from anything of this kind.
It does not appear that Racine read much philosophy, as he
should have done, but he occasionally did some business in
superintending building operations at Chevreuse, the duke's
country house. He would seem, however, to have been already
given up irrecoverably to literature. This by no means suited
the views of his devout relations at Port Royal, and he complains
in one of his letters that an unlucky sonnet on Mazarin had
brought down on him “excommunications sur excommunications.”
The marriage of Louis XIV. was the occasion of an
ambitious ode, La nymphe de la Seine, which was submitted
before publication to Jean Chapelain, the too famous author of
the Pucelle. Chapelain made many suggestions which Racine
duly adopted. Nor did the ode bound his ambitions, for in
1660 he finished one piece, Amasie, and undertook another,
Les Amours d'Odile, for the theatre. The first, however, was
rejected by the actors of the Marais, and it is not certain that the
other was ever finished or offered to those of the Hôtel de
Bourgogne. Racine's letters show that he was intimate with
more than one actress at this time; he also made acquaintance
with La Fontaine, and the foundations at any rate of the
legendary “society of four” (Boileau, La Fontaine, Molière
and Racine) were thus laid.

His relations were pretty certainly alarmed by this very
dreadful worldliness, though a severe expostulation with
him for keeping company with the abominable actors is perhaps
later in date. Racine was accordingly disturbed in his easy-
going life at Paris. In November 1661 he went to Uzès in
Languedoc to live with his uncle the Père Scouin, vicar-general
of that diocese, whose attempts to secure a benefice for his
son were, however, in vain. Racine was back in Paris before
the end of 1663. His letters from Uzès to La Fontaine to
Le Vasseur, and others are in much the same strain as
before, but there is here and there a marked tone of cynicism
in them. He also attempted a little courtiership. An ode
on the recovery of Louis XIV. from a slight illness probably
secured him the promise of a pension, of which he speaks to his
sister in the summer of 1664. It is uncertain whether this
pension is identical with “gratifications” which we know that
Racine for some years received, and which were sometimes
eight and sometimes six hundred livres. It would seem not,
as one of these gratifications had been allotted to him the year
before he so wrote to his sister. The ode in which he thanked
the king for his presents, La Renommée, is said to have intro-
duced him to Boileau, to whose censorship there is no doubt
that he owed much, if not everything; and from this date,
November 1663, the familiarity of “the four” seems to have
existed in full force. Unfortunately it is precisely at this date
that correspondence ceases, and it is not renewed till after
the close of his brief but brilliant career as a dramatist (Esther
and Athalie excepted). From this time forward the gossip
of the period, and the Life by his son Louis, are the chief sources
of information. Unfortunately Louis Racine, though a man of
some ability and of unimpeached character, was only six years
old when his father died, and had no direct knowledge.
Still his account represents family papers and traditions; and seems
to have been carefully, as it is certainly in the main impartially,
written. From other sources—notably Boileau, Claude
Brossette and Jean Baptiste de Valincourt—a good deal of
pretty certainly authentic information is obtainable, and there
exists a considerable body of correspondence between Boileau
and the poet during the last ten years of Racine's life.

This, the first but the last characteristic of the dramas by
which Racine is known, La Thébaïde, was finished by the end of 1663,
and on Friday 20th June 1664 it was played by Molière's com-
pany at the Palais Royal theatre. Some editors assert that
Molière himself acted in it, but the evidence is not the same
as the cast we have, and that is sixty years after, omits his name,
though those of Madeleine Béjard and Madeleine de Brie
occurred. There is also a tradition that Molière suggested the
subject; but Louis Racine distinctly says that his father
wrote most of the play at Uzès before he knew Molière. From
Racine's own earlier letters it appears that the play was de-
signed for the rival theatre, and that “La Déchéance,” Racine's
familiar name for Madeleine de Beauchâte, with whom
he was intimate, was to play Antigone. The play itself is by
far the weakest of Racine's works. He has borrowed much
from Euripides and not a little from Jean de Rotrou; and in
his general style and plan he has as yet struck out no great
variation from Corneille. It was acted twelve times during
the first month, and was occasionally revived during the year
following. This is apparently the date of the pleasant picture
RACINE, JEAN

of the four friends which La Fontaine draws in his *Psyche*, Racine figuring as Acante, "qui aimait extrêmement les jardins, les fleurs, les ombres," in which surroundings he helped to compose the lampoon *Chapellen décorté* on a writer who had helped him with criticism, obtained royal gifts for him, and, in a fashion, started him in the literary career.

We have no definite details as to Racine's doings during the year 1664, but in February 1665 he read at the Hôtel de Nevers before La Rochefoucauld, Madame de la Fayette, Madame de Sévigné, and other scarcely redoubtable judges the greater part of his second acted play, *Alexandre le Grand*, or, as Pomponne (who tells the fact) calls it, *Porus*. It was anxiously expected by the public, and Molière's company played it on the 4th of December—Monsieur, his wife Henrietta of England, and many other distinguished persons being present. The gazetteer, Adrien Perdou de Subligny vouches for its success, and the receipts were good and steady. But a fortnight afterwards *Alexandre* was played, "de complott avec M. Racine," says La Grange, by the rival actors (who had four days before performed it in private) at the Hôtel de Bourgogne. A vast amount of ink has been spilt on this question, but no one has produced any valid justification for Racine. That the piece failed at the Palais Royal, as is stated in the earliest attempt to excuse Racine, and the only one made in his lifetime, is not true. His son simply says that he was "mecontent des acteurs," which indeed is self-evident. It is certain that Molière and he ceased to be friends in consequence of this proceeding; and that Molière was in fault no one who has studied the character of the two men will easily believe. If, however, *Alexandre* was the occasion of showing the defects of Racine's character as a man, it raised him vastly in public estimation as a poet. He was now for the first time proposed as a serious rival to Corneille. There is a story that he read the piece to the author of the *CID* and asked his verdict. Corneille praised the piece highly, but not as a drama, "Il l'assurait qu'il n'était pas propre à la poésie dramatique." There is no reason for disbelieving this, for the character of Alcide was to have failed to shock Corneille, and he was notorious for not miring his words. The contrast between the two even at this early period was accurately apprehended and put by Saint Evremond in his masterly *Dissertation sur l'Alexandre*, but this was not published for a year or two. To this day it is the best criticism of the faults of Racine, though not, it may be, of the merits, which had not yet been fully seen. It may be added that in the preface of the printed play the poet showed the extreme sensitiveness to criticism which perhaps excuses, and which certainly often accompanies, a tendency to criticize others. These defects of character showed themselves still more fully in another matter. The Port Royalists, as has been said, detested the theatre, and in January 1666 Nicole, their chief writer, spoke in one of his *Lettres sur les visionnaires*, directed against Dumaresq of Saint-Sulon, of dramatic poets as "empoisonneurs publics." Racine immediately published a letter to La Grange, in which he protested. Racine had contented himself with protesting against the exaggeration of the decriers of the stage there would have been little harm done. But he filled the piece with personalities, telling an absurd story of Mère Angélique Arnault's supposed intolerance, drawing a ridiculous picture of Le Maître (a dead man and his own special teacher and friend), and sneering savagely at Nicole himself. The latter made no reply, but two lay adherents of Port Royal took up the quarrel with more zeal than discretion or ability. Racine wrote a second pamphlet as bitter and personal as the first, but less amusing, and was about to publish it when fortunately Bolieu, who had been absent from Paris, returned and protested against the publication. It remained accordingly unprinted till after the author's death, as well as a preface to both which he had prepared with a view to publishing them together and so discharging the accumulated resentment arising from a long course of "excommunications."

After this disagreeable episode Racine's life, for ten years and more, becomes simply the history of his plays, if we except his liaisons with the actresses Mademoiselle du Parc and Mademoiselle de Champtesné, and his election to the Academy on the 17th of July 1673. Mademoiselle du Parc (Anduchis de Gorda) was no very great actress, but was very beautiful, and she had previously captivated Molière. Racine induced her to leave the Palais Royal company and join the Hôtel. She died in 1668, and long afterwards the infamous Catherine Voisin accused Racine of having poisoned her. Mademoiselle de Champtesné was plain, but an admirable actress, and apparently very attractive in some way, for not merely Racine but Charles de Sévigné and many others adored her. For five years before his marriage Racine seems to have been her *aman en titre*, but long afterwards, just before his own death, when he heard of her mortal illness, he spoke of her to his son without a flash of tenderness.

The series of his unquestioned dramatic triumphs began with *Andromaque*, and this play may perhaps dispute with *Phèdre* and *Athalie* the title of his masterpiece. It is much more uniformly good than *Phèdre*, and the character of Hermione is the most personally interesting on the French tragic stage. It is said that the first representation was on 10th November 1667, in public and by the actors of the Hôtel de Bourgogne, but the first contemporary mention of it by the gazettes, prose and verse, is on the 17th, as performed in the queen's apartment. Perrault, by no means a friendly critic as far as Racine is concerned, says that it made as much noise as the *CID*, and so it ought to have done. Whatever may be thought of the *tragédie pathétique* (a less favourable criticism might call it the "sentimental tragedy"), it could hardly be better exemplified than in this admirable play. A ferocious epigram of Racine's own tells us that some critics thought Pyrrhus too fond of his mistress, and Andromache too fond of her husband, but in the contemporary deprecations is to be found the avowal of its real merit. Pyrrhus was taken by Floridor, the best tragic actor by common consent of his time, and Orestes by Montlauré, also an accomplished player. But Mademoiselle de Champtesné, who played Andromache, had generally been thought below, not above, her parts, and Mademoiselle des Oeilllets, who played the difficult rôle of Hermione, was old and had few physical advantages. No one who reads *Andromaque* without prejudice is likely to mistake the secret of its success, which is, in few words, the application of the most delicate art to the conception of really tragic passion. Before leaving the play it may be mentioned that it is said to have been in the part of Hermione, three years later, that Mademoiselle de Champtesné captivated the author. *Andromaque* was succeeded, at the distance of not more than a year, by the charming comedietta of *Les Plaidieurs*. We do not know exactly when it was played, but it was printed on the 5th of December 1668. Many anecdotes are told about its origin and composition. The *Wasps* of Aristophanes, and the known fact that Racine originally destined it, not for a French company, but for the Italian troupe which was then playing the *Commedia dell'arte* in Paris, give the background for the invention on which it is said to have been based. These fragments of Racine's imagination are not traceable in the play. The result is a piece admirably dramatic, but sufficiently literary to shock the *profusion vulga*, which too frequently gives the tone at theatres. It failed completely, the chief favouring voice being, according to a story sufficiently well attested and worthy of belief even without attestation, that of the man who was best qualified to praise and who might have been most tempted to blame of any man then living. Molière, says Valincourt, the special friend of Racine, said in leaving the house, "Que ceux qui se moquent de cette pièce meritoient qu'on se moqueur d'eux." But the piece was suddenly played at court a month later; the king laughed, and its fortunes were restored. It need only be added that, if Louis XIV. admired *Les Plaidieurs*, Napoleon did not, and excluded it from his travelling library. It was followed by a very different work, *Britannicus*, which appeared on 15th December 1669. This was much less successful than *Andromaque*, and seems to have held its own but a very few nights. Afterwards it became very popular, and even from the first the
exquisite verisimilitude was not denied. But there is no doubt that in Britannicus the defects of Racine display themselves pretty clearly to any competent critic. The complete nullity of Britannicus himself and of Junie, and the insufficient attempt to display the complex and dangerous character of Nero are not redeemed by Agrippina, who is really good, and Burrhus, who is solidly painted as a secondary character. Voltaire calls it “la pièce des connaisseurs,” a double-edged compliment. The next play of Racine has, except Phèdre, the most curious history of all. “Bérénice,” says Fontenelle succinctly, “fut un duel,” and he acknowledges that his uncle was not the conqueror. Henrietta of Orleans proposed (it is said without letting them know the double commission) the subject to Corneille and Racine at the same time, and rumour gives no very creditable reasons for her choice of the subject. Her death preceded the performance of the two plays, both of which, but especially Racine’s, were successful. There is no doubt that it is the better of the two, but Claude Chapelle’s unfriendly criticism in quoting the two lines of an old song—

“Marion pleure, Marion crie,
Marion veut qu’on la marie”

is said to have annoyed Racine very much, and it has a most malicious appropriateness. Bajazet, which was first played on 4th January 1672, is perhaps better. As a play, technically speaking, it has great merit, but the reproach commonly brought against its author was urged specially and with great force against this by Corneille. It is impossible to imagine anything less Oriental than the atmosphere of Bajazet; the whole thing is not only French but ephemeral French—French of the day and hour; and its ingenious scenario and admirable style scarcely save it. This charge is equally applicable with the same reservations to Mithridate, which appears to have been produced on 13th January 1673, the day after the author’s reception at the Academy. It was extremely popular, and Racine could hardly have lodged a more triumphant diploma piece. His next attempt, Iphigénie, was a long step backwards and upwards in the direction of Andromaque. It is not that the characters are eminently Greek, but that Greek tragedy gave Racine examples which prevented him from flying in the face of the propriety of character as he had done in Bérénice, Bajazet, and Mithridate, and that he here called in, as in Andromaque, other passions to the aid of the mere sighing and crying which form the sole appeal of these three tragedies. It succeeded brilliantly and deservedly, but, oddly enough, the date of its appearance is very uncertain. It was acted at court on the 18th of August 1674, but it does not seem to have been given to the public till the early spring of 1675.

The last and finest of the series of tragedies proper was the most unlucky. Phèdre was represented for the first time on New Year’s Day 1677, at the Hôtel de Bourgogne. Within a week the opposition company, or troupe du roi, launched an opposition Phèdre by Nicolas Pradon. This singular competition, which had momentous results for Racine, and in which he to some extent paid the penalty of the lex talionis for his own rivalry with Corneille, had long been foreseen. Racine had from the first been bitterly opposed, and his enemies at this time had the powerful support of the duchess of Bouillon, one of Mazarin’s nieces, together with her brother the duke of Nevers and divers other personages of high position. These persons of quality, guided, it is said, by Madame Deshoulières, selected Pradon, a dramatist of little talent but of much facility, to compose a Phèdre in competition with which it was known that Racine had been elaborating. The partisans on both sides did not neglect means for correcting fortune. On her side the duchess of Bouillon is accused of having bought up the front places in both theatres for the first six nights; on his, Racine is said to have prevailed on the best actresses of the company that played Pradon’s piece to refuse the title part. There is even some ground for believing that he endeavoured to prevent the opposition play from being played at all. It was of no value, but the measures of the cabal had been so well taken that the finest tragedy of the French classical school was all but driven from the stage, while Pradon’s was a positive success. A war of sonnets and epigrams followed, during which it is said that the duke of Nevers menaced Racine and Boileau with the same treatment which Dryden and Voltaire actually received, and was only deterred by the protection which Condé extended to them.

The unjust cabal against his piece no doubt made a deep impression on Racine. But it is impossible to decide exactly how much influence this had on the subsequent change in his life. For thirteen years he had been constantly employed on a series of brilliant dramas. He now broke off his dramatic work entirely and in the remaining twenty years of his life wrote but two more plays, and those under special circumstances and of quite a different kind. He had been during his early manhood a libertine in morals and religion; he now married, became irreproachably domestic, and almost instinctively devout. No authentic account of this change exists; for that of Louis Racine, which attributes the whole to a sudden religious impulse, is manifestly little more than the theory of a son, pious in both senses of the word. Probably all the motives which friends and foes have attributed entered more or less into his action. At any rate, what is certain is that he reconciled himself with Arnauld and Port Royal generally, accepted, with whatever sincerity, their doctrine of the incompatibility of the stage and the Christian life, and on the 1st of June married Catherine de Romanet and definitely settled down to a quiet domestic life, alternated with the duties of a courtier. For his repentence was by no means a repentance in sackcloth and ashes. The drama was not then very profitable to dramaticists, but Louis Racine tells us that his father had been able to furnish a house, collect a library of some value, and save 6000 livres. His wife had money, and he had possessed for some time (it is not certain how long) the honourable and valuable post of treasurer of France at Moulins. His annual gratification had been increased from 800 to 1500 livres, then to 2000, and in the October of the year of his marriage he and Boileau were made historiographers-royal with a salary of 2000 crowns. Besides all this he had, though a layman, one or two benefices. It would have been pleasant if Louis Racine had not told us that his father regarded His Majesty’s choice as “an act of the grace of God to detach him entirely from poetry.” For the historiographer of Louis XIV. was simply his chief flatterer. However, little came of this historiography. The joint incumbents of the office made some campaigns with the king, sketched plans of histories and left a certain number of materials and memoirs; but they executed no substantive work. Racine, whether this be set down to his credit or not, was certainly a humble and apparently an adroit courtier. His very relapse into Jansenism coincided with his rise at court, where Jansenism was in no favour, and the fact that he had been in the good graces of Madame de Montespan did not deprive him of those of Madame de Maintenon. Neither in Esther did he hesitate to reflect upon his former patroness. But a reported sneer of the king, who was sharp-eyed enough, “Cavoie avec Racine se croit bel esprit; Racine avec Cavoie se croit courtisan,” makes it appear that his comparatively low birth was not forgotten at Versailles.

Racine’s first campaign was at the siege of Ypres in 1678, where some practical jokes are said to have been played on the two civilians who acted this early and peculiar variety of the part of special correspondent. Again in 1683, in 1687 and in each year from 1691 to 1693 Racine accompanied the king on his various campaigns. The literary results of these have been spoken of. His labours brought him, in addition to his other gains, frequent special presents from the king, one of which was as much as 1000 pistoles. In 1690 he further received the office of “gentilhomme ordinaire du roi,” which afterwards passed to his son. Thus during the later years of his life he was more prosperous than is usual with poets. His domestic life appears to have been a happy one.
Louis Racine tells us that his mother “did not know what a verse was,” but Racine certainly knew enough about verses for both. They had seven children. The eldest, Jean Baptiste, was born in 1678; the youngest, Louis, in 1692. It has been said that he was thus too young to have many personal memories of his father, but he tells one or two stories which show Racine to have been at any rate a man of strong family affection, as, moreover, his letters prove. Between the two sons came five daughters, Marie, Anne, Elizabeth, Françoise and Madeleine. The eldest, after showing “vocation,” married in 1699, Anne and Elizabeth took the veil, the youngest two remained single but did not enter the cloister. To complete the notice of family matters—much of Racine’s later correspondence is addressed to his sister Marie, Madame Rivière.

The almost complete silence which Racine imposed on himself after the comparative failure of Phédre was broken once or twice even before the appearance of his two last exquisite tragedies. The most honourable of these was the reception of Thomas Corneille on 2nd January 1685 at the Academy in the room of his brother. The discourse which Racine then pronounced turned almost entirely on his great rival, of whom he spoke even more than becomingly. But it was an odd conjunction of the two reigning passions of the latter part of his life—devotion and obsequiousness to the court—which made him once more a dramatist. Madame de Maintenon had established an institution, first called the Maison Saint Louis, and afterwards (from the place to which it was transferred) the Maison de Saint Cyr, for the education of poor girls of noble family. The tradition of including acting in education was not obsolete. At first the governor, Madame de Grignon, composed pieces for representation, but, says Madame de Caylus, a witness at first hand and a good judge, they were “detestable.” Then recourse was had to chosen plays of Corneille and Racine, but here there were obvious objections. The favourite herself wrote to Racine that “nos petites filles” had played Andromaque a “a great deal too well.” She asked the poet for a new play suited to the circumstances, and, though Boileau advised him against it, it is not wonderful that he yielded. The result was the masterpiece of Esther, with music by Moreau, the court composer and organist of Saint Cyr. Although played by schoolgirls and in a dormitory, it had an enormous success, with which it may be charitably hoped that the transparent comparison of the patroness to the heroine had not too much to do. Printed shortly afterwards, it had to suffer a certain reaction, or perhaps a certain vengeance, from those who had not been admitted to the private stage. But no competent judge could hesitate. Racine probably had some and to some extent followed the Andromaque of Antoine de Montchrestien, but he made of it only the use which a proved master in literature has a perfect right to make of his forerunners. The beauty of the chorus, which Racine had restored more probably from a study of the Pléiade tragedy than from classical suggestions, the perfection of the characters and the wonderful art of the whole piece need no praise. Almost immediately the poet was at work on another and a still finer piece of the same kind, and he had probably finished Athalie before the end of 1690. The fate of the play, however, was very different from that of Esther. Some fuss had been made about the worldliness of great court fêtes at Saint Cyr, and the new play, with settings as before by Moreau, was acted both at Versailles and at Saint Cyr with much less pomp and ceremony than Esther. It was printed in March 1691, and the public cared very little for it. The truth is that the last fifteen and twenty years of the reign of Louis XIV. was marked by one of the lowest tides of literary accomplishment and appreciation in the history of France. The just judgment of posterity has ranked Athalie, if not as Racine’s best work (and there are good grounds for considering it to be this), at any rate as equal to his best. Thenceforward Racine was practically silent, except for four cantiques spirituels, in the style and with much of the merit of the choruses of Esther and Athalie. The general literary sentiment led by Fontenelle (who inherited the errors of Corneille, his uncle, and whom Racine had taken charge of) was against the arrogant critic and the irritating poet, and they made their case worse by espousing the cause of La Bruyère, whose personalities in his Caractères had made him one of the best-hated men in France, and by engaging in the Ancient and Modern battle with Charles Perrault. Racine, moreover, was a constant and spiteful epigrammatist, and the unlucky habit of preferring his joke to his friend struck by him to the last. A savage epigram on the Soséris of Hilaire Bernard de Longpierre, who had done him no harm, was his familiar acquaintance, and had actually put him above Corneille in a parallelité between them, dates as late as 1695. Still the king maintained him in favour, and so long as this continued he could afford to laugh at Grub Street and the successors of the Hôtel de Rambouillet alike. At last, however, there seems to have come a change, and it is even probable that royal displeasure had some effect on his health. Discharge of the liver appears to have been the immediate cause of his death, which took place on 12th April 1699. The king seems to have, at any rate, forgiven him after his death, and he gave the family a pension of 2000 livres. Racine was buried at Port Royal, but even this transaction was not the last of his relations with that famous home of religion and learning. After the destruction of the abbey in 1711 his body was exhumed and transferred to Saint Étienne du Mont, his gravestone being left behind and only restored to his ashes a hundred years later, in 1818. His eldest son was never married; his eldest daughter and Louis Racine have left descendants to the present day.

Racine may be considered from two very different points of view,—(1) as a playwright and poetical artist, and (2) as a dramatist and a poet. From the first point of view there is hardly any praise too high for him. He did not invent the form he practised, and those who, from want of attention to the historical facts, assume that he did are unskillful as well as ignorant. When he came upon the scene the form of French plays was settled, partly by the energetic efforts of the Pléiade and their successors, partly by the reluctant acquiescence of Corneille. It is barely possible that the latter might, if he had chosen, have altered the course of French tragedy; it is nearly certain that Racine could not. But Corneille, though he was himself more responsible than any one else for the acceptance of the single-situation tragedy, never frankly gave himself up to it, and the inequality of his work is due to this. His heart was, though not to his knowledge, elsewhere, and with Shakespeare, Racine, in whom the craftsman dominated the man of genius, worked with a will and without any misgivings. Every advantage of which the Senecan tragedy adapted to modern times was capable he gave it. He perfected its versification; he subordinated its scheme entirely to the one motive which could have free play in it,—the display of a conventionally intense passion, hampered by this or that obstacle; he set himself to produce in verse a kind of Ciceroian correctness. The grammar-criticisms of Vaugelas and the taste-criticisms of Boileau produced in him no feeling of revolt, but only a determination to play the game according to these new rules with triumphant accuracy. And he did so play it. He had supremely the same faculty which enabled the rhétoriqueurs of the 15th century to execute apparently impossible tours de force in ballades couronnées; and similar tricks. He had besides a real and saving vein of truth to nature, which preserved him from tricks pure and simple. He would be, and he was, as much a poet as prevalent taste would let him be. The result is that such plays as Phèdre and Andromaque are supreme in their own way. If the critic will only abstain from thrusting in tincture, when according to the particular rules he ought to thrust in quart, Racine is sure to beat him.

But there is a higher game of criticism than this, and this game Racine does not attempt to play. He does not even attempt the highest poetry at all. His greatest achievements in pure passion—the foiled desires of Hermione and the jealous frenzy of Phèdre—are cold, not merely beside the crossed love
of Ophelia and the remorse of Lady Macbeth, but beside the sincerer if less perfectly expressed passion of Corinne’s Cléopâtre and Camille. In men’s parts he fails still more completely. As the decency of his stage would not allow him to make his heroes frankly heroic, so it would not allow him to make them utterly passionate. He had, moreover, cut away from himself, by the adoption of the Senecan model, all the opportunities which would have been offered to his remarkably variegated talent on a freer stage. It is indeed tolerably certain that he never could have achieved the purely poetical comedy of As You Like It or the Vida es Sueña, but the admirable success of Les Plaideurs makes it at least probable that he might have done something in a lower and a more conventional style. From all this, however, he deliberately cut himself off. Of the whole world which he could have known, he retained and employed as materials for his dramas only the conventional fraction. Within these narrow bounds he did work which no admirer of literary craftsmanship can regard without admiration. It would be unnecessary to contrast his performances with his limitations so sharply if those limitations had not been denied. But they have been and are still denied by persons whose sentence carries weight, and therefore it is still important to point out the fact of their existence.

**BIBLIOGRAPHY.**—Nearly all Racine’s works are mentioned in the above notice. There is here no room for a bibliographical account of his editions. An attempt to collect them seems to have been made by d’Olivet, who in 1719 published a list of the first collected editions, which was in 1675-76, and contained the nine tragedies which had then appeared. The last and most complete which appeared in the poet’s lifetime (1697) was perhaps revised by him, and contains the critical edition of the tragedies published in 1698. Thus the edition of 1698 is left in 2 vols. 12mo. The posthumous editions are innumerable, and gradually became more and more complete. The most noteworthy are the Amsterdam edition of 1722; that by Abbé d’Olivet, also at Amsterdam, 1743; the Paris quart of 1760; the edition of Luneau de Boisjermyn, Paris and London, 1768; the magnificent illustrated folios of 1805 (Paris); the edition of Germain Garnier with La Harpe’s commentary, 1807; Geoffroy’s of 1819; the edition of 1820; and lastly, the Grandes écrivains edition of Paul Mesnard (Paris, 1865-73). This last contains almost all that is necessary for the study of the poet, and has been chiefly used in preparing the above notice. Louis Racine’s Life was first published in 1747. Translations and imitations of Racine are innumerable. In English the Distressed Mother of Ambrose Phillips and the Phaedra and Hippolytus of Edmund Smith (1672-1716), both composed more or less under Addison’s influence, are the most noteworthy.

As for criticism on him, a bibliography of it would be nearly a bibliography of French critical literature. The chief recent instance of such a work is that of Labro (1880) and Écrivains français (1889), but F. Brunetiére, Emile Faguet, and other critics have constantly and in various ways endeavoured to apply the general reaction from Romanticism to a semi-classical attitude to this greatest of French “classics.” The conclusions above-mentioned remain unaffected by this temporary set of opinion. Racine will never be “enfonce” —“put to rout”—as the extravagant Romantics thought him to be for a time. But, on the other hand, his limitations, his meanness, and his ingenuity are but arbitrary and inspired by a theory of drama as to “conflicts of will” and the like can suffice to veil his defect in universality, his comparative shallowness, and his inadequate appreciation, or at least representation, of the richness, the intricacy and the unconventionality of nature.

(G. S. A.)

**RACINE, LOUIS** (1639-1715), French poet, second son of Jean Racine, was born in Paris on the 6th of November 1639. Early conscious of a vocation for poetry, he had been dissuaded from following his inclination by Boileau on the ground that the gift never existed in two successive generations. In 1722 his small means induced him to accept a position in the revenue in Provence, but a marriage with a certain Mademoiselle Presle secured his independence. In 1755 he lost his son in the disasters consequent on the Lisbon earthquake. This misfortune, commemorated by Écoutard Lebrun, broke Racine’s spirit. He sold his library, and gave himself up entirely to the practice of religion. In 1710 he had become a member of the Académie des Inscriptions, but had never offered himself as a member of the Académie Française, for fear, it is said, of incurring refusal on the part of Goldscheider (1728) and Religion (1742), his most important work, are inspired with a sincere piety, and are written in verse of uniform clearness and excellence. His other works include epistles, odes, among which the Ode sur l’harmonie (1736) should be mentioned, Mémoires (1747) of Jean Racine, and a prose translation of Paradise Lost (1755). Louis Racine died on the 29th of January 1793. He was characterized by Voltaire as “le bon versificateur Racine, fils du grand poète Racine.”

His Œuvres complètes were collected (6 vols.) in 1808.

**RACINE, city and the county-seat of Racine county, Wisconsin, U.S.A., on the W. shore of Lake Michigan at the mouth of the Root river, about 25 m. S.S.E. of Milwaukee and about 60 m. N. of Chicago. Pop. (1890) 21,014; (1900) 29,102, of whom 9242 were foreign-born; (1910) census, 38,002. Racine is served by the Chicago & North Western and the Chicago, Milwaukee & St Paul railways, by two interurban electric railways, connecting with Milwaukee and Chicago, and by steamboat lines. The river has been deepened and its mouth protected by breakwaters, providing an excellent harbour; in 1909 vessels drawing 19 ft. could pass through the channel. Among the public buildings are the City Hall, the County Court House, the Federal Building, the Carnegie Library, the High School, two hospitals and the Taylor Orphan Asylum. Among educational institutions, besides the public schools, are Racine College (Protestant Episcopal, 1853), St Catherine’s Academy (Roman Catholic) and two business colleges. Racine is, next to Milwaukee, the most important manufacturing centre in Wisconsin. The value of its factory products in 1905 was $164,458,065, an increase of 41% over that of 1900. Of this, $5,117,079 (or 31.5% of the city’s total) represented agricultural implements and machinery. Carriages and wagons ($2,729,311) and automobiles ranked next in importance.

Racine was the French form of the name of the Root river. The first Europeans positively known to have visited the site of Racine were Vincennes, Tonty and several Jesuit missionaries, who stopped here for a time on their way down the coast in 1609. Early in the 19th century Jambeau, a French trader, established himself on the Root river, and in 1834 Gilbert Knapp (1798-1866), who had been a lake captain since 1818, induced several residents of Chicago to make their homes at its mouth. The place was at first called Port Gilbert. The settlement grew rapidly, a sawmill was built in 1835, and the present name was adopted in 1837. In 1841 Racine was incorporated as a village and in 1848 was chartered as a city.

See S. S. Hurlburt, Early Days at Racine (Racine, 1872); History of Racine and Kenosha Counties (Chicago, 1879).

**RACK,** an homonymous word of which the principal branches are the words meaning (1) a mass of cloud driving before the wind in the upper air, (2) to draw off wine or other liquor from the lees, (3) a bar or framework of bars, (4) an instrument of torture. The etymology of (1) shows that it is ultimately to be connected with “wreck” and “rack,” drifted seaweed, and means that which is driven by or drifts with the wind; cf. Norw. rak, wreckage, refuse, Icel. reka, to drive, toss. In (2) the term seems to have come from the German weg, weg, to drive away (from trade, etc., Skt: Eym. Diet. 1070) points out, and was adapted from Prov. arracc, to devastate, desert. In (3) the terms and husks of grapes, drags. Both (2) and (3) are in origin to be connected. The O.E. reccan and Ger. rekken mean “to stretch,” and so “rack” means something stretched out, a straight bar or rail, especially a toothed bar gear with a cog-wheel, a framework of bars, as in the cradle of upright bars in which fodder can be placed for cattle, and the instrument of torture, which in Ger. is Recke or Rackschrank. The “rack” for torture was an oblong frame of wood, slightly raised from the ground, having at one end a fixed bar to which the legs were fastened, and at the other a movable bar to which the hands were tied. By means of pulleys and levers this latter could be rolled on its own axis, thus straining the ropes till the sufferer’s joints were dislocated. Its first employment in England is said to have been due to John Holland, 4th duke of Exeter, constable of the Tower in 1447, whence it was popularly known as “the Duke of Exeter’s daughter.”
RACKETT—RACQUET

In 1628 the whole question of its legality was raised by the attempt of the privy council to rack John Felton, the assayer of the duke of Buckingham. The judges resisted, unanimously declaring its use to be contrary to the laws of England.

RACKETT, or Rackett-Bassoon (Fr. ceresel or ceresol; Gcr. Rockett, Rankett or Wurfsagott), a kind of dwarf bassoon, now obsolete, with a body measuring only from 4 to 11 in. in length, but nevertheless containing the necessary length of tubing to give the bassoon or contra-bassoon pitch. The rackett consists of a barrel-like body, resembling the barrel drone of the musette (see BAGPIPE), made of wood or ivory. Round a centre tube are grouped eight parallel channels of very narrow cylindrical bore communicating with each other and forming a continuous tube nine times the length of the small body.

A reed mouthpiece in combination with a cylindrical tube invests the latter with the acoustic properties of a closed pipe by creating a node at the mouthpiece, and the fundamental note given by such a tube is, therefore, an octave deeper in pitch than would be an open pipe of the same length. The bassoon has a conical bore and the properties of the open pipe where the aggregate length of the channels in the rackett only requires to be half that of the bassoon, a physical phenomenon to which this curious freak owes its existence. In the rackett the holes are bored obliquely through from the channels to the circumference—three in front for the left and three for the right hand, with an additional hole for the little finger; while at the back are placed the vent and the three holes, one for the left thumb and two for the right, the second hole being controlled by the ball of the thumb. The rackett is played by means of a large double reed placed under a birevettet or cap, so that the lips do not come into contact with the reed, but only send a stream of compressed air into the birevettet, whereby the reed is set in vibration. The back of the reed is made of a new principle of construction, peculiar to the bagpipe chanter and drones (with a slight variation) and to cromornes, hautbois de Poitou and a few other obsolete instruments, is that no harmonics can be obtained, since the vibrating length and the tension of the reed cannot be controlled by the player; the compass is therefore obtained by means of the fundamental and of the ten holes of the instrument, aided by cross-fingering.

RAQUETS, or Rackets, a game played in an enclosed court with a ball and an implement with which the ball is struck called a racquet, from which the game takes its name. The racquet is about 3 ft. long, the head, which was formerly pear-shaped, being in the modern racquet nearly circular, from 7 to 8 in. in diameter and tightly cross-strung with cat-gut. The balls, which are about 1 1/4 in. in diameter, are made of strips of cloth tightly wound over each other, with a sewn covering of smooth white leather, the floor and walls of English courts being coloured black; in India, where the floor and walls of the court are painted white, black balls are used. There are no regulation dimensions for a racquet court, nor for the racquet or ball, though substantial uniformity is observed in practice. The game is usually played either by two or by four players; and in England the court is the same for the four-handed and the two-handed game, the floor measuring usually 60 ft. by 30 ft., or occasionally an inch or two more each way; but in America larger courts measuring on the floor 80 ft. by 40 ft., a size formerly not uncommon in England, are sometimes built for the four-handed game. Modern racquet courts have four walls and a roof, though in India they are sometimes left unroofed for the sake of coolness. The floor, which must be perfectly level and smooth, should be made of cement; but is sometimes paved, with less perfect results. The floor cannot be too hard, since the faster the ball travels the better the game; similarly the walls, which should be built of masonry faced with cement and most carefully smoothed, cannot be too hard and fast. The front and side walls are about 30 ft. high, the back wall being about half that height, with a gallery for spectators (containing the marker's and umpires' box) above it. The court is entered by a door in the centre of the back wall, which when shut must be perfectly flush with that wall, and without any projecting judge. The court is lighted from the roof. The diagram (fig. 2) shows the divisions and markings of the court. On the front wall is fixed a wooden board, the upper edge of which, 26 in. from the floor, constitutes the "play-line," and which usually fills the whole space from that height to the floor; and at a height from the floor of 8 ft. or a few inches more is a second line, called the "cut-line" or "service-line," painted white or in colour. At a distance of 38 ft. (in a court 60 ft. by 30 ft.) from the front wall and parallel to it, a white line is painted on the floor from wall to wall called the "short-line"; and from the centre of the short-line to the centre of the back wall is the "fault-line," dividing into two equal rectangles the space between the back wall and the short-line. These rectangles are the service-courts and are called the right-hand and left-hand court respectively. Against the side walls outside these courts, but so that one side in each case is formed by the short-line, are squares 8 ft. by 8 ft. called the service-boxes.

The Game.—Racquets is usually played either by two persons ("singles"), or four persons playing two against two ("doubles"); and the general idea of the game is the same as that in tennis, lawn tennis and fives, the object of the player in all these games being to score a point by striking the ball either before it reaches the ground or on its first bound, in accordance with the rules of the game, in such a way that his adversary may fail to make a "good," i.e. a valid, stroke in return. In the four-handed game one of each set of partners takes the right-hand court and his partner the left. The game consists of 15 points called "aces." Aces can only be scored by the "hand-in," (the player or partners having the "innings"), and the "hand-out" must therefore win a stroke or strokes to obtain innings before he or they can score an ace; in "doubles" each of the partners has an innings, and both must therefore be ousted before "hand-out" obtains the innings; but to this rule the first innings of each game affords an exception (see below). The "hand-in" always has "service," i.e. he opens the rally (the "rally" being the series of strokes made alternately by the two sides until one or other of them fails to make a good return) by "serving" the ball from the hand. This first serve, or "serve," must be made in the following manner. The server, standing with one foot at least inside one of the service-boxes, must toss the ball from his hand, and while it is in the air he must hit it with his racquet so that it strikes the front wall above the service-line and falls to the floor within the service-court on the opposite side; after striking the front wall the ball may, but need not, strike the side wall or back wall, or both, and it may do so either before or after touching the floor. The serve is a "fault" if the ball (1) strikes the front wall

white, black balls are used. There are no regulation dimensions for a racquet court, nor for the racquet or ball, though substantial uniformity is observed in practice. The game is usually played either by two or by four players; and in England the court is the same for the four-handed and the two-handed game, the floor measuring usually 60 ft. by 30 ft., or occasionally an inch or two more each way; but in America larger courts measuring on the floor 80 ft. by 40 ft., a size formerly not

1 The word comes, through Fr. raquette, from Sp. and Port. raqueta. The origin is doubtful, but Arab. rahan, palm of the hand, has been suggested; "fives" played with the hand long preceded the game with a bat; cf. also Fr. name for fives, paume.
above the board but on or below the service-line, in which case it is called a "cut"; or (2) touches the floor on the first bound, outside the proper service-court, when it is called "short" or "fault" according to the position of its pitch (see below). If the "hand-out" player to whom the fault is served "takes" it (i.e. if he plays at it), the fault is condoned and the play proceeds as if the serve had been good. If, however, the fault be not taken, the server must serve again from the same box; and if he serves a second fault he loses his "hand" or innings, and his partner or his opponent, as the case may be, takes his place. Two consecutive faults have thus the same result as the loss of a stroke in the rally by the "hand-in." A serve which makes the ball strike the board, or the floor before reaching the front wall, or which sends it "out-of-court" (i.e. into the gallery or roof of the court), counts the same as two consecutive faults; it costs the server his innings. Skill in service is a most important part of proficiency in racquets; a player can hardly become first-rate unless he possesses a "strong service." As in tennis a great deal of "cut" may be imparted to the ball by the stroke of the racquet, which makes the ball in its rebound from the wall behave like a billiard ball carrying "side" when striking a cushion; and when this "cut" is combined with great pace in the bound of the ball off the side wall, the back wall, and the floor, at varying angles which the server has to a great degree under his control, it becomes exceedingly difficult for hand-out to "get up" the serve (i.e. to hit it on the first bound, sending it above the play-line on the back wall), and still more so to make a good stroke which will render it difficult for his adversary in his turn to get up the ball and thus continue the rally. It often happens, therefore, that a long sequence of aces, sometimes the whole 15 aces of a game, are scored consecutively by a serve which hand-out is unable to return. A noteworthy instance of successful service occurred in the semifinal tie of the doubles Amateur Championship matches at the Queeh's Club in 1897 when W. L. Foster opened service and scored all the aces in the first two games, and added six in the third, thus putting on a sequence of 36 aces before losing his "hand." To obtain first innings is therefore an initial advantage, although in doubles it is limited by the rule that only one partner shall have a "hand" (innings) in the opening service.

The question which side shall have this advantage is decided by spinning a racquet, the "rough" and "smooth" sides of which take the place of "heads" and "tails" when a coin is tossed. The side winning the spin opens the game by serving as described above. The server may begin in either of the service boxes but when the service has been started, the server must proceed from the two boxes alternately till the close of the innings of the side, whether singles or doubles. When the other side obtains the innings they may in like manner begin in either box, without regard to where the last service of their opponents was delivered. In singles, hand-out changes sides in the court after each serve, answering to the change over of the server; in doubles the serve is taken alternately by the two hand-out players, who permanently occupy the right- and left-hand courts respectively, being allowed to change the order in which they receive the service only once in any game, or at the end of any game or rubber. Except in the very rare case of left-handed players most of the play in the left half of the court, including the taking of all service on that side, is back-handed; and the stronger of the two partners in back-hand play usually therefore takes the left-hand court. The best position in the court for the hand-out about to take the serve depends entirely on the nature of the service, and he has to use his judgment the instant the ball leaves the server's racquet in order to determine where it will strike the floor and at what precise point in its course it will be best for him to attempt to take it. A strong fast service, heavily cut, that sends the ball darting round the corner of the court, leaving the back wall at an extremely acute angle, or dropping almost dead off it, can only be got up by standing near the back wall a long way across the court and taking the ball by a wrist stroke at the last instant before it falls to the ground a second time. On the other hand when the server avoids the side wall altogether and strikes the back wall direct and hard, whether he achieves a "nick" serve (i.e. the ball striking precisely in the angle between the back wall and the floor) or hits the wall high up, hand-out will have little time to spare in changing position to get within reach of the ball. Some good players make a practice wherever possible, especially in the case of heavily cut service, of taking the serve on the volley (i.e. before the ball reaches the ground), sometimes of taking the ball after it leaves the side wall and before it reaches the back wall; practice alone enables the player to decide with the necessary promptitude how each stroke is to be played. In returning the serve, or in playing any stroke during the rally, the ball may strike any of the other walls before the front wall; but though this "boasted" stroke is quite legitimate, and is sometimes the only way of getting up a difficult ball, it is not considered good style deliberately to slash the ball round the corners in order to keep it in the fore end of the court. Good play consists for the most part in hard low hitting, especially as close as possible along the side walls into the corners of the back wall. One of the most effective strokes in racquets is the "drop," which means that the ball is hit so that it only just reaches the front wall and drops close to it, while the player conceals his intention by appearing to strike hard. "The drop-stroke," says Mr Eustace Miles, who regrets that it is less cultivated than formerly, "is one of the most beautiful, and of all drop-strokes, the volley or half-volley is the best." The "half-volley," in which the ball is struck at the moment of its contact with the floor and before it has had time to rise, is also employed with great effect in hard play; it makes the return much quicker than when the ball is allowed to rise to the full length of the court, and requires corresponding quickness on the part of the adversary. It sometimes happens, too, that the player finding himself too near the pitch of the ball to take it at the end of the bound, yet not near enough to volley it, is compelled to take it on the half-volley as the only chance of getting it up. Accuracy in volleying and half-volleying, especially if the ball be kept low, is a most difficult art to acquire, but a good long rally in which are included a number of hard rapid half-volleys within a couple of inches of the board, is the prettiest feature of the game.

If hand-out succeeds in returning the serve, the rally proceeds until one side or the other fails to make a good return. A good return means (1) that the ball is struck by the racquet before its second bound on the front, and without its having touched any part of the clothes or person of the striker or his partner; (2) that it is hit before the ball reaches the front wall above the height of the service box; (3) that the server's opponent is not in the court; and (4) that it returns off the front wall properly (i.e. to the floor of the court or to an adversary's racquet) without going out of court. If hand-in be the one to fail in making a good return, he loses his "hand," or innings, and (in singles) hand-out goes in and proceeds to serve; in doubles one of the hand-in partners loses his "hand," and the second partner goes in and serves till he in turn similarly loses his "hand," except that in the case of the opening service in the game there is (as already mentioned) only one "hand" in any event. If hand-out fails to make a good return to the serve or to any stroke in the rally, hand-in scores an ace, and the side that first scores 15 aces wins the game. When, however, the score reaches "13-all" (i.e. when each side has scored 13 aces), hand-out may, before the next serve is delivered, declare that he elects to "set" the game either to 5 or 3, whichever he prefers, and similarly when the score stands at "14-all," hand-out may "set" the game to 3. He makes this declaration by calling "set-5!" or "set-3!" and it means that 5 aces, or 3 aces, as the case may be, shall be required to win the game.

In the confined space of a racquet court it is not always easy, especially in doubles, for the players to avoid obstructing each other. It is provided in the rules that "each player must get out of his opponent's way as much as possible," and that it shall be a "let" (an Old English word for impediment or hindrance) and "the service or rally shall count for nothing," and the server shall serve again from the same service-box,
(a) if the ball in play touch the striker’s opponent on or above the knee, and if in the marker’s opinion it be thereby prevented from reaching the front wall above the board (the play-line); or (b) if either player unduly obstruct his opponent from returning the ball served in play.” If a player considers that he has been thus obstructed by his opponent he may “claim a let,” and the marker adjudicates his claim. The marker’s decision is final; but “if in doubt which way to decide, the marker may direct that the ace be played over again.” It is the duty of the marker, who occupies a box in the gallery, to “call the game.” As soon as the server serves the ball the marker calls “Play!” if the ball strikes the front wall above the service-line; and “Cut!” if it strikes below the service-line; if the ball falls in front of the short-line the marker calls “Short!”; if the wrong side of the fault-line he calls “Fault!”; but whether it be “cut,” “short,” or “fault,” the serve counts as a fault in its effect. To every good return, as to every good serve, the marker calls “Play!” If a return is made after the second bound of the ball (called a “double”) the marker calls “Double!” or “Not up!”; if the ball is hit into the gallery, or against its posts or cushions, or above the girders or cross-beams of the roof, he calls “Out-of-court!” At the end of every rally he calls the state of the game, always naming first the score of hand-in—“One-love,” meaning the server has scored one ace and is in the lead; “Two-love,” “Three-love,” “Four-love,” “Five-all,” “Five-five,” “Fourteen-eleven,” and so on, till one side has scored 15, when the marker calls “Game!” He then in similar fashion calls the state of the match—“Two games to one,” or whatever it may be—before the commencement of the next game. The server in possession at the end of the game continues to serve in the new game, subject as before to the rule limiting the first innings of the game to a single “hand.” The usual number of games in matches is five for singles, and seven for doubles. In matches where there are umpires and a referee, there is an appeal to them from the marker’s decision except as regards questions relating to the service, on which the marker’s decision is final.

Records.—Attempts have been made to trace racquets, like tennis, to an ancient origin; but although it is doubtless true that the striking of a ball with the hand or some primitive form of bat is one of the oldest forms of pastimes, and that racquets has been evolved from such an origin, the game as now known can hardly be said to have been in existence before the 19th century. John Smart’s book The Sports and Pastimes of the People of England, published at the beginning of the 19th century, makes no mention of racquets; and the century was far advanced before the racquet court was promoted from being an adjunct of the pot-house and the gasolier, in which connection the court within the purloins of the Fleet prison has been immortalized in the pages of Pickwick, to a position scarcely less dignified than that of the tennis-court with its royal and historical associations. It was at the public schools that racquets first obtained repute. The school courts were at first unroofed, and in some cases open also at the back and sides, or on one side. Among the most famous of the early racquets professionals, before the period of the modern closed court, were Robert Mackay (1820), the brothers Thomas and John Pittman, J. Lamb, J. C. Mitchell and Francis Erwood (1860). One of the most famous matches ever played at racquets was that in which Erwood was beaten by Sir William Hart-Dyke, who used the “drop” stroke with telling effect, and who, after representing Oxford in the first four inter-university matches, was the only amateur racquet player who ever defeated the open champion. A notable state in the history of racquets was the year 1858, when the court at the old Prince’s Club in Han Place, London, was built. Here the annual racquet matches between Oxford and Cambridge Universities, singles and doubles, were first played in 1858, and the Public Schools Championship (doubles only) ten years later. Modern racquets may perhaps be said to date from the time of the brothers Gray, who as professionals greatly raised the standard of skill in the game, and as teachers at the schools and universities improved the play of amateurs. William Gray beat Foulkes, the champion of America, in 1857; Henry Gray and Joseph Grayfield also in that latter year was beaten by H. B. Fairs ("Punch") but held the championship from 1858 to 1887. Another member of the same family was Walter Gray, who was as distinguished for the power of his stroke as his brother William was for the accuracy of his “drop” and the ease and grace of his volley and half-volley. Walter Gray was followed in the championship by Peter Latham, the first professional to combine the open Tennis Championship with the Racquets Championship; and in the opinion of Mr Eustace Miles ‘there has probably lived no player who could have beaten him at either game.’ Latham was the first to use the heavily cut service at racquets, and he is also remarkable for the power of his wrist stroke. In the last twelve years or so of the 19th century Latham stood alone, and in the opinion of the best judges he was the greatest of all racquet players. When once he had won the championship he never lost it, and when at last he resigned his title he was succeeded by Gilbert Browne, a player of a decidedly inferior calibre, who in 1903 was challenged and beaten by an Indian marker called Jamsetji. For the next six years, during which time Latham was away, comparatively little was heard of professional racquets; but in 1910 interest was revived by a handicap at Queen’s Club for a prize of £100, in which Peter Latham himself took part, and which was won by Jennings of Aldershot. As a result of this contest a challenge was issued by W. Hawes, the marker at Wellington College, to play any other professional for £200 a side and the championship of England. The challenge was accepted by C. Williams, a young player of Prince’s Club, who easily won the match, and with it the title of champion.

The institution of annual matches between Oxford and Cambridge Universities in 1858, and of the Public Schools Championship in 1868, gave an immense stimulus to the game among amateurs. Of the amateur players, from 1858 to 1908, Oxford won 26 and Cambridge 25; of the 52 contests in doubles Oxford won 25 and Cambridge 27. Among the public schools Harrow has been far the most successful, having won the championship on seven occasions, and on 19 occasions the cup 19 times out of 42 contests. Moreover, under the condition permitting any school winning in three consecutive years to retain the challenge cup permanently, Harrow became possessed of three cups, having won the championship 1897–1914 inclusive, 1897–1915 inclusive, and 1883–1887 inclusive. Of the next most successful school has been Eton, eight times champion; Charterhouse having won five times, and no other school more than three times. For the first twenty years of the contest, with a single exception when Rugby won in 1890, Eton and Harrow have been the main rivals; and it is not surprising therefore that the majority of famous amateurs learnt the game at one or other of these schools. Among Etonians were W. Hart-Dyke, C. J. Ottaway, the Hon. Alfred Lyttelton, the Hon. Ivo Bligh (afterwards Lord Darnley), C. T. Studd and H. Philipson; Harrow has produced R. D. Walker, one of the best of the earliest amateur racquet players, C. F. Buller, T. S. Dury, A. J. Weble, M. C. Kemp, E. M. Butler, the brothers Eustace Craven and H. E. Crawley, H. M. Lease, Percy Ashworth and C. Browning. The famous Malvern family of Foster has been as conspicuous in the racquet court as on the cricket field, the eldest, H. K. Foster, being probably the finest amateur player of the generation. Of the generation that followed, E. H. Cooper-Key, Colonel Spens, E. M. Baerlein and Eustace Craven have also been in the front rank of amateur players. The opening of the Queen’s Club, West Kensington, was a notable event in the history of the game, especially as it was followed by the establishment of amateur championships in singles and doubles in 1889, of which the results have been as follows:

A military championship was inaugurated in 1903 and is played annually at Princes' Club. In 1908, mainly through the exertions of Major A. Cooper-Key, a "Tennis, Racquets and Fives Association" was founded for the purpose of encouraging these games, safeguarding their interests and providing a legislative body whose authority would be recognized by all the natural racquet players.

Racquets in America.—In the United States and in Canada racquets is a popular game, and among the leading athletic clubs have good courts. The American champions Foulkes, Bouker and George H. Foster are all English professionals, but had a great reputation in their own country; and Tom Pettitt, Ellis and Moore are names that stand high in the records of the game. Among American amateurs, Lamontayne did much to encourage racquets in New York in the early period of its history; and in more recent times Quincy Shaw, de Garmondia, R. Fearing, Payne Whitney, Mackay, L. Waterbury and P. D. Haughton have shown themselves racquet players of very high merit, although Mr. Eugene Miles is of opinion that "an English player like H. K. Foster, or Dames Longworth, or Ashworth, would give any American amateur upwards of seven aces."

Squash racquets is a form of the game which provides admirable practice for the beginner, and has advantages of its own which offer attractions even to those who are proficient players of real racquets. It is played with a hollow india-rubber ball about the size of a fives ball (i.e. nearly twice the size of an ordinary racquet ball) and with a racquet rather shorter in the handle than those used in racquets proper. The court may be of any dimensions, but is always much smaller than a real racquet court; the squash ball, being not nearly so fast as the racquet ball, would not reach the back wall in a 60 ft. court on the first bound unless hit high as well as hard against the front wall. The rules of the game itself are precisely the same as in real racquets. Squash racquets originated at Harrow, where the boys were in the habit of playing in an improvised court in the corner of the school-yard against the old school building; the windows, buttresses and water-pipe on the face of the wall forming irregularities which developed great skill on the part of the players in taking advantage of the difficulties thus caused. The marked success of Harrow in the Public Schools Championship at racquets, especially during the first twenty years of its institution (see above), has been attributed to the early training and practice gained at squash racquets in the school-yard, and in other courts which came into use as the popularity of this form of the game increased. Towards the end of the 19th century squash racquets became adopted at other schools and at the universities; and as the court is much cheaper to build than that required for real or "hard ball" racquets, and the game is cheaper as well as easier to play, many private clubs came into existence. Of the numerous clubs which arose in the early 1890's, several squash courts were provided at the Bath Club, London, where handicap tournaments are annually played. At Lord's cricket ground, when a new pavilion was erected in 1890, squash racquet courts were included in the building. The dimensions of the courts at Lord's, which may be taken as the best model, are as follows: length 42 ft. by 24 ft.; height of back wall 8 ft. 8 in.; height of service-line from floor 8 ft. 9 in.; height of play-line 2 ft. 4 in. The short-line is 23 ft. from the front wall. The place which squash racquets has come to occupy may be estimated from the fact that Mr. Eustace Miles pronounces it "an almost indispensable preparation" for tennis and racquets as those games are played under modern conditions; and the same authority sufficiently describes its merits when he observes that it "gives, at a small cost of time or money, abundance of hard and brisk and simple yet exciting exercise for all times of life, of the year, and even of the day—if we have good artificial light." The squash courts at Lord's and at the Bath Club are lighted by electricity, so that play is not dependent on the condition of the atmosphere, or on the season of the year.

See Tennis, Lawn Tennis, Rackets and Fives in the "Badminton Library"; Racquets, Tennis and Squash, by Eustace Miles (London, 1902); Sporting and Athletic Register (London, 1908). (R. J. M.)

RADAUTZ, a town in Bukovina, Austria, 35 m. S. by W. of Czernowitz by rail. Pop. (1900) 14,334, of which about 70% are Germans and 25% are Rumanians. It was formerly the seat of a Greek bishopric, removed to Czernowitz in 1786, and possesses a cathedral (1402) with the tombs of several Moldavian princes. The Austrian government has here a large stud. To the W. of Radautz are situated the old monasteries of Putna and Suczawica, dating from the 15th century. They still contain many old and valuable ecclesiastical objects of art, although a great part has been removed to the various monasteries in Moldavia.

RADBERTUS PASCHASII (d. c. 860), French theologian, was born at or near Soissons towards the close of the 8th century. He became a monk of Corbie, near Amiens in Picardy, in 814, and assumed the cloister name of Paschasius. He gained recognition as a learned and successful teacher, and the younger Adalhard, St Anskar the apostle of Sweden, Odo bishop of Beauvais and Warinus abbot of Corvei in Saxony may be mentioned among the more distinguished of his pupils. Between 842 and 846 he was chosen abbot, but as a disciplinarian he was more energetic than successful, and about 851 he resigned the office. He never took priestly orders. He died and was buried in Corbie.

Radbertus is one of the most important theologians in the history of the church. "He was perhaps the most learned and able theologian after Alcuin, as well versed in Greek theology as he was familiar with Augustinianism, a comprehensive genius, who felt the liveliest desire to harmonize theory and practice, and at the same time give due weight to tradition" (Harnack). His great work, De institutione clericorum et Dominorum (first ed. 831; new ed., with an epistle to Charles the Bald, 844), which was not only the first systematic and thorough treatise on the sacrament of the eucharist, but is the first clear dogmatic statement of transubstantiation, and as such opened an unending controversy. It was at once attacked by Ratramnus and Hrabanus Maurus, but was so completely in touch with the practice of the church and the spirit of the age, as to win the verdict of Catholic orthodoxy.

On the eucharistic controversy see the article on Radbertus by Streitz in Herzog-Hauck's Real-Encyklopädie; Bach, Dogmengeschichte der Kirche, vol. 1, p. 365 ff.; Cornut, Die Lehre des 6, Paschasius Radbertus v. d. Eucharistie (1866); Renz, Die Geschichte des Messopferbegriffs (1901); K. G. Goetz, Die Abendmahlsfrage in ihrer gescheichtlichen Entwicklung (1904), a complete survey of the whole problem, beginning with Radbertus. A. Harnack's treatment in his History of Dogma (vol. v., p. 308 ff.) is clear and appreciative.

RADCLIFFE, ANN (1764-1823), English novelist, only daughter of William and Ann Ward, was born in London on the 9th of July 1764. She was the author of three famous novels: The Romance of the Forest (1791), The Mysteries of Udolpho (1794) and The Italian (1797). When she was twenty-three years old she married William Radcliffe, an Oxford graduate and student of law. He gave up his profession for literature, and afterwards became proprietor and editor of the English Chronicle. After The Italian she gave up writing for publication, and was reported to have been driven mad
by the horrors of her own creations, but the nearest approach to eccentricity on Mrs Radcliffe's part was dislike of public notice. Of scenery Mrs Radcliffe was an enthusiastic admirer; and she made driving tours with her husband every other summer through the English counties. She died on the 7th of February 1823. In the history of the English novel, Mrs Radcliffe holds an interesting place. She is too often confounded with her imitators, who vulgarized her favourite "properties" of rambling and ruinous old castles, dark, desperate and cadaverous villains, secret passages, vaults, trapdoors, evidences of deeds of monstrous crime, sights and sounds of mysterious horror. She deserves at least the credit of originating a school of which she was the most distinguished exponent; and none of her numerous imitators approach her in ingenuity of plot, fertility of incident or skill in devising apparently supernatural occurrences capable of explanation by human agency and natural coincidence. She had a genuine gift for scenic effect, and her vivid imagination provided every tragic situation in her stories with its appropriate setting. Sir Walter Scott wrote an appreciative essay for the edition of 1834, and Miss Christina Rossetti was one of her admirers. She exercised a great influence on her contemporaries, and "Scheleoni!" in The Italian is one of the prototypes of the Barthesian's "traps", "doorways", and "secret vaults.

**RADCLIFFE, SIR GEORGE** (1593–1657). English politician, son of Nicholas Radcliffe (d. 1599) of Overthorpe, Yorkshire, was educated at Oldham and at University College, Oxford. He attained some measure of success as a barrister, and about 1626 became the confidential adviser of Sir Thomas Wentworth, afterwards earl of Strafford, who was related to his wife, Anne Trappes (d. 1659). Like his master he was imprisoned in 1627 for declining to contribute to a forced loan, but he shared the good, as well as the ill, fortunes of Wentworth, acting as his adviser when he was president of the council of the north. When Wentworth was made lord deputy of Ireland, Radcliffe, in January 1633, preceded him to that country, and having been made a member of the Irish privy council he was trusted by the deputy in the fullest possible way, his advice being of the greatest service. In 1640, Radcliffe, like Strafford, was arrested and was impeached, but the charges against him were not pressed, and in 1643 he was with Charles I. at Oxford. He died at Flushing in May 1657. Radcliffe wrote An Essay towards the life of my Lord Strafford, from which the material for the various lives of the statesman has been largely taken.

Sir T. D. Whitaker, Life and Correspondence of Sir G. Radcliffe (1810).

**RADCLIFFE, JOHN** (1659–1714), English physician, was born at Wakefield in 1650. He matriculated at University College, Oxford, and after taking his degree in 1669 was elected to a fellowship at Lincoln College, which he gave up in 1677 when, under the statutes of the college, he was called on to take orders. Graduating in medicine in 1675, he practised first in Oxford, but in 1684 removed to London, where he soon became one of the leading physicians. He frequently attended William III. until 1699, when he caused offence by remarking, as he looked at the King's swollen ankles, that he would not have his legs for his three kingdoms. On the 1st of November 1714 he died of apoplexy at his house in Carshalton. By his will he left property to University College for founding two medical travelling fellowships and for other purposes. Other property was put at the disposal of his executors to use as they thought best, and was employed, among other things, in building the Radcliffe Observatory, Hospital and Library at Oxford, and in enlarging St Bartholomew's Hospital. John Radcliffe was elected M.P. for Bamber in 1690 and for Buckingham in 1713.

**RADCLIFFE,** an urban district in the Radcliffe-cum-Farnworth parliamentary division of Lancashire, England, on the river Irwell, 2 m. S.S.W. of Bury, on the Lancashire & Yorkshire railway. Pop. (1901) 25,368. The church of St Bartholomew dates from the time of Henry IV.; some of the Norman portions of the building remain. Cotton-weaving, calico-printing, and bleaching, dyeing, paper-making, iron-founding and machine-making are the principal industries, and there are extensive collieries in the neighbourhood.

**RADEBERG,** a town of Germany, in the kingdom of Saxony, pleasantly situated in a fertile district on the Röder, 10 m. N.E. of Dresden, by the railway to Görlitz and Breslau. Pop. (1905) 13,301. It has an Evangelical and a Roman Catholic church, and an old castle. Its principal industries are the manufacture of glass, machinery, furniture, and paper, and it produces a light Pilsener beer which is largely exported. Near the town are the Augustusbad and the Hermannsbad, two medicinal springs.

**RADEGUNDA, ST** (d. 587), Frankish queen, was the daughter of Berthaire, king of the Thuringians. Berthaire was killed by his brother Hermannfried, who took Radegunda and educated her, but was himself slain by the Frankish kings Theuderic and Clotaire (529), and Radegunda fell to Clotaire, who later married her. Her piety was already so noteworthy that it was said that Clotaire had married a nun, not a queen. She left him when he unjustly killed her brother, and fled to Medardus, bishop of Poitiers, who, notwithstanding the danger of the act, consecrated her as a nun. Radegunda stayed in Poitiers, founded a monastery there, and lived for a while in peace. Here Venantius Fortunatus, the Italian poet, found a friendly reception, and two of the poems printed under his name are usually attributed to Radegunda. From him we gain a most pleasing picture of life at the monastery. The queen died on the 13th of August 587.

See the references in A. Molière, Sources de l'Histoire de France.

**RADETSKY, JOSEF, COUNT of RADETZ (1766–1838).** Austrian soldier, was born at Trzebnitz in Bohemia in 1766, to the nobility of which province his family, originally Hungarian, had for several centuries belonged. Orphaned at an early age, he was educated by his grandfather, and after the old count's death, at the Theresa academy at Vienna. The academy was dissolved during his first year's residence, and he joined the army as a cadet in 1785. Next year he became an officer, and in 1787 a first lieutenant in a cuirassier regiment. He served as a gallipot on Lacy's staff in the Turkish War, and in the Low Countries during the Revolutionary War. In 1795 he fought on the Rhine. Next year he served with Beaulieu against Napoleon in Italy, and inwardly rebelled at the indecisive "cordon" system of warfare which his first chief, Lacy, had instituted and other Austrian generals only too faithfully imitated. When his regiment was completely overthrown, at Fleurus he had led a party of cavalry through the French lines to discover the fate of Charleroi, and at Vellecchio on the Mincio, with a few 'husars, he rescued Beaulieu from the midst of the enemy. Promoted major, he took part in Wurmser's Mantua campaign, which ended in the fall of the place. As lieutenant-colonel and colonel he displayed both bravery and skill in the battles of the Trebbia and Novi (1799), and at Marengo, as colonel on the staff of Melas, he was hit by five bullets, after endeavouring on the previous evening to bring about modifications in the plan suggested by the "scientific" Zach. In 1801 Radeztsky received the knighthood of the Maria Theresa order. In 1805, on the march to Ulm, he received news of his promotion to major-general and his appointment to a command in Italy under the archduke Charles, and thus took part in the successful campaign of Caldiero. Peace again afforded him a short leisure, which he used in studying and teaching the art of war. In 1806, now a lieutenant field marshal, he fought at Wagram, and in 1810 he received the commandership of the Maria Theresa order and the colonelcy of the 5th Radeztsky hussars. From 1809 to 1812, as chief of the general staff, he was active on the Russian front, but unable to carry out the reforms he desired owing to the opposition of the Treasury, he resigned the post. In 1813 he was Schwarzenberg's chief of staff, and as such had considerable influence on the councils of the Allied sovereigns and generals. Langenau, the quartermaster-general of the Grand Army, found him an indispensable assistant, and he had a considerable share in planning the Leipzig campaign and as a tactician won great praises in the
battles of Brienne and Arcis sur Aube. He entered Paris with the allied sovereigns in March 1814, and returned with them to the congress of Vienna, where he appears to have acted as an intermediary between Metternich and the czar Alexander, when these great personages were not on speaking terms.

During the succeeding years of peace he disappeared from the public view. He resumed his functions as chief of the staff, but his ardent ideas for reforming the army came to nothing in the face of the general war-weariness and desire to "let well alone." His zeal added to the number of his enemies, and in 1829, after he had been for twenty years a lieutenant field marshal, it was proposed to place him on the retired list. The emperor, unwilling to go so far as this, promoted him general of cavalry and shielded him by making him governor of a fortress. But very soon afterwards the restoration settlement of Europe was shaken by Belgian revolts, and Radetzky was brought into the field of war again. He took part under Frimont in the campaign against the Papal States insurgents, and succeeded that general in the chief command of the Austrian army in Italy in 1834. In 1836 he became a field marshal. He was now seventy years of age, but he displayed the activity of youth in training and disciplining the army he commanded. But here too he was in advance of his time, and the government not only disregarded his suggestions and warnings but also refused the money that would have enabled the finest army it possessed to take the field at a moment's notice. Thus the events of 1848 in Italy, which gave the old field marshal his place in history among the great commanders, found him, in the beginning, not indeed unprepared but seriously handicapped in the struggle with Charles Albert's army and the insurgents. How by falling back to the Quadrilateral and there, checking one opponent after another, he was able to spin out time until reinforcements arrived, and how thenceforward up to the final triumph of Novara on the 23rd of March 1849, he and his army carried all before them, is described in the article ITALIAN WARS. The well-disciplined sense of duty to the superior officer, which was remarked even in the brilliant and sanguine young army reformer of 1810, had become more intense in the long years of peace, and after keeping his army loyal in the midst of the confusion of 1848, he made no attempt to play the part of Wallenstein or even to assume Wellington's rôle of family adviser to the nation. While as a patriot he dreamed a little of a united Germany, he remained to the end simply the commander of one of the emperor's armies. He died, still in harness, though infirm, on the 5th of January 1858.

In military history Radetzky's fame rests upon one great achievement, but in the history of the Austrian army he lives as the frank and kindly "Vater Radetzky" whom the soldiers idolized. He was fortunate in the moment of his death. In the year following, another and a greater Italian war broke out, his beloved army, disintegrated by peace economies which the old field marshal had been unable any longer to redress by ceaseless personal training, and in addition suffering from divided command and confused staff work, was defeated in every encounter.

RADEVORMWALD, a town of Germany, in the Prussian Rheinlandkreis, 10 m. E. from Remscheid, on the branch line of railway from Krebsberg. Pop. (1905) 6,788. It consists of the town proper and of several suburbs, and has five Evangelical and two Roman Catholic churches. Its chief manufactures are skates, files, locks and similar articles, and it has also cloth and cotton factories.

See J. H. Becker, Geschichte der Stadt Radevormwald (Cologne, 1864).

RADHANPUR, a native state of India, in the Palanpur agency, Bombay. It is situated in the north-western corner of Gujarat, close to the Runn of Cutch. The country is an open plain without hills and with few trees. It contains an area of 1130 sq. m. with a population in 1901 of 61,548, showing a decrease of 37% during the decade, due to the results of famine. The estimated revenue is £27,000. The chief products are cotton, wheat and the common varieties of grain; the only manufacture of any importance is the preparation of a fine description of saltpetre. Radhanpur first came under British protection in 1813. The chief, whose title is Nawab, belongs to the Babi family, who have held power in Gujarat for more than two centuries. The town of Radhanpur had a population in 1901 of 11,879. It is a walled town, with an export trade in rape-seed, grain and cotton.

RADIANT, a term introduced by Cuvier in 1812 to denote the lowest of his four great animal groups or "embranchements." He defined them as possessing radial instead of bilateral symmetry, and as apparently destitute of nervous system and sense organs, as having the circulatory system rudimentary or absent, and the respiratory organs on or co-extensive with the surface of the body; he included under this title and definition five classes—Echinodermata, Acalepha, Entozoa, Polypi and Infusoria. Lamarck (Hist. nat. d. Anim. s. Vertébrés) also used the term, as when he spoke of the Medusae as radiata medusaria et anomalies; but he preferred the term Radiaria, under which he included Echinodermata and Medusae. Cuvier's term in its wide extension, however, passed into general use; but, as the anatomy of the different forms became more fully known, the difficulty of including them under the common designation made itself increasingly obvious. Milne-Edwards removed the Polypoia; the group was soon further thinned by the exclusion of the Protozoa on the one hand and the Entozoa on the other; while in 1848 Leuckart and Frey clearly distinguished the Coelenterata from the Echinodermata as a separate sub-kingdom, thus condemning the usage by which the term Radiata was still continued to be applied to these two groups at least. In 1855, however, Owen included under Lamarck's term Radiaria the Echinodermata, Anthozoa, Acalepha and Hydrozoa, while Agassiz also clung to the term Radiata as including Echinodermata, Acalepha and Polypi, regarding their separation into Coelenterata and Echinodermata as "an exaggeration of their anatomical differences" (Essay on Classification, London, 1859). These attempts, however, to perpetuate the usage were finally discredited by Huxley's important Lectures on Comparative Anatomy (1864), in which the term was finally abolished, and the "radiate mob" finally distributed among the Echinodermata, Polyzoa, Vermes (Platyhelminthes), Coelenterata and Protozoa.

RADIATION, THEORY OF. The physical activities that follow the absorption of radiation, and their energy, in a form which is highly available thermodynamically, is derived from the radiation of the sun. This has been ascertained to be dynamic energy, transmitted in waves by the vibrations of a medium occupying space, as the energy of sound is transmitted by the vibrations of the atmosphere. The elasticity that transmits it may be assumed to be mathematically perfect: any slight loss in transit of the light from the most distant stars, which recent statistical comparisons of brightness with distance may possibly indicate, is to be explained far more suitably by the presence of nebulous matter than by any imperfection of the aether. The latter would thus be the one perfect frictionless medium known to us: it could not be such if it were constituted, like matter, of independent molecules. It is probable that the electromagnetic wave of which the disturbance is a simple vibration, would be a disturbance of space itself. A molecule of matter is a kinetic system compounded of simpler elements: its energy may be classified into constitutive energy essential to its continued existence, and vibratory energy which it can receive from or radiate away into aether. A piece of matter isolated in free aether would in time lose all energy of the latter type by radiation; but the former will remain so long as the matter persists, along with the energy of the uniform translatory motion to which it is ultimately reduced. Thus all matter is in continual exchange of vibratory energy with the aether: it is with the laws of this exchange of energy that the general theory of Radiation deals, as distinguished from the mechanism of the aetheral vibrations, which is usually treated as the Theory of Light (see AETHER).
RADIATION

at independently by Balfour Stewart and Kirchhoff about the year 1858, that the constitution (§ 6) of the radiation which pervades an enclosed, surrounded by bodies in a steady thermal state, must be a function of the temperature of those bodies, and of nothing else. It was subsequently pointed out by Stewart (Brit. Assoc. Report, 1871) that if the enclosure contains a radiating and absorbing body which is put in motion, all being at the same temperature, the constituents of the radiation in front of it and behind it will differ in period on account of the Doppler-Fizeau effect, so that there will be an opportunity of gaining mechanical work in its settling down to an equilibrium; there must thus be some kind of thermodynamic compensation, which might arise either from aetherial friction, or from work required to produce the motion of the body against pressure exerted on it by the surrounding radiation. The hypothesis of friction is now excluded in ultimate molecular physics, while the thermodynamic bearing of a pressure exerted by radiation, such as is demanded by Maxwell's electric theory, has been more recently developed on other lines by Bartoli and Boltzmann (1884), and combined with that of the Doppler effect by W. Wien (1893) in development of the ideas above expressed.

The original reasoning of Stewart and Kirchhoff rests on the dynamical principle, that by no process of ordinary reflexion or transmission can the period, and therefore the wave-length, of any harmonic constituent of the radiation be changed; each constituent remains of the same wave-length from the time it is emitted until the time it is again absorbed. If we imagine a field of radiation to be enclosed within perfectly reflecting walls, then, provided there is no material substance in the field which can radiate and absorb, the constitution of the radiation in it may be any whatever, and it will remain permanent. It is only the presence of material bodies that by their continued emission and absorption can transform the surrounding radiation towards the unique constitution which corresponds to their temperature. We can define the temperature of an isolated field of radiation, of this definite ultimate constitution, to be the same as that of the material bodies with which it would thus be in equilibrium. Further, the mutual independence of the various constituents of any field of radiation enclosed by perfect reflectors allows us to assign a temperature to each constituent, such as the part involving wave-lengths lying between \( \lambda \) and \( \lambda + \delta \lambda \); that will be the temperature of a material system with which this constituent by itself is in equilibrium of emission and absorption.

But to reason about the temperature of radiation in this way we must be sure that it completely pervades the space, and has ensured by the continuous reflectors from the walls of the enclosure. The question of the temperature of a directed wave-train travelling through space, such as a beam of light, will come up later. The temperature of each constituent in a region of unidirected radiation is thus a function of its wave-length and its intensity alone. It is the fundamental principle of thermodynamics, that temperatures tend to become uniform. In the present case of a field of radiation, this equalization cannot take place directly between the various constituents of the radiation that occupy the same space, but only through the intervention of the emission and absorption of material bodies; the constituent radiations are virtually partitioned off adiabatically from direct interchange. Thus in discussing the transformations of temperatures of the constituent elements of radiation, we are really reasoning about the activity of material bodies that are thermal equilibrium with those constituents, the theoretical basis of the idea of temperature, as depending on the fortuitous residue of the energy of molecular motions, is preserved.

2. Mechanical Pressure of Undulatory Motions.—Consider a wave-train of any kind, in which the displacement is \( \xi = a \cos m(x+ct) \) so that it is propagated in the direction in which \( x \) decreases; let it be directly incident on a perfect reflector travelling towards it with velocity \( v \), whose position is therefore given at time \( t \) by \( x = ut \). There will be a reflected train given by \( \xi' = a' \cos m'(x-c't) \), the velocity of propagation \( c' \) being of course the same for both. The disturbance does not travel into the reflector, and must therefore be annulled at its surface; thus when \( x = ut \) we must have \( \xi + \xi' = 0 \) identically. This gives \( a' = -a \), and \( m'(c-v) = m(c+v) \). The amplitude of the reflected disturbance is therefore equal to that of the incident one; while the wave-length is altered on the ratio \( \frac{c-v}{c+v} \), which is approximately \( 1 - \frac{v^2}{c^2} \) where \( u/c \) is small, and is thus in agreement with the usual statement of the Doppler effect.

The energy in the wave-train being half potential and half kinetic, it is given by the integration of \( p(c/c+1) \) along the train, where \( p \) represents density. In the reflected train it is therefore augmented, when equal lengths are compared, in the ratio \( \frac{c+v}{c-v} \); but the length of the train is diminished by the reflexion in the ratio \( \frac{c-v}{c+v} \), hence on the whole the energy transmitted per unit time is increased by the reflexion in the ratio \( \frac{c+v}{c-v} \). This increase per unit time can arise only from work done by the advancing reflector against pressure exerted by the radiation. That pressure, per unit surface, must therefore be equal to the fraction \( \frac{2}{c} \) of the energy in a length \( c+v \) of the incident wave-train; thus it is the fraction \( \frac{c-v}{c+v} \) of the total density of energy in front of the reflector, belonging to both the incident and reflected trains. When \( v \) is small compared with \( c \), this makes the pressure equal to the density of vibrational energy, in accordance with Maxwell's electrodynamic formula (Elec. and Mag., 1871).

The argument may be illustrated by the transverse vibrations of a tense cord, the reflector being then a lamina through a small aperture in which the cord passes; the lamina can thus slide along the cord and sweep the vibratory motion in front of it. In this case the force acting on the lamina is the resultant of the tensions \( T \) of the cord on the two sides of the aperture, giving a lengthwise force \( \frac{4Td(x+\xi')}{dx} \) when, as usual, powers higher than the second of the ratio of amplitude to wave-length are neglected; this, when \( w/c \) is small, is an oscillatory force of amount \( sp(c/c+1) \), whose time-average agrees with the value above obtained. If we consider a finite train of waves thus sent back from a moving reflector, the time integral of the pressure must represent force transmitted along the cord, or a gain of longitudinal momentum in the reflected waves, or both together.

When it is a case of transverse waves in an elastic medium, reflected by an advancing obstacle, the origin of the working pressure is not so obvious, because we cannot easily formulate a mechanism for the advancing reflector like that of the lamina above employed. In the case of light-waves we can, however, imagine an ideal material body, constituted of very small molecules, that would sweep them in front of it with the same perfection as a metallic mirror actually reflects the longer Hertzian waves. The pressure will then be identified physically, as in the case of the latter waves, with the mechanical forces acting on the screening oscillatory electric current-sheet which is induced on the surface of the reflector. The displacement represented above by \( \xi \), which is annulled at the reflector, may then be taken to be either the tangential electric force or the normal component of the vector whose velocity is the magnetic force. The latter interpretation is theoretically interesting, because that vector, which is the dynamical displacement in electron-theory, usually occurs only through its velocity. The general case of oblique incidence can be treated on similar lines; each filament of radiation (ray) in fact exerts its own longitudinal push equal to its energy per unit length, and it is only a matter of summation.

The usual formula for the pressure of electric radiation is
derived from a theory, namely, that of the ordinary electro-dynamic equations, which considers the velocity of the matter, or rather of the electrons associated with it, to be so small compared with that of radiation that the square of the ratio of these velocities can be neglected. The formula above obtained is of general application, and shows that for high values of $v$ the pressure must fall off. It has been urged as an objection to the thermodynamic reversibility of a ray (§ 8) that the work of the radiant pressure exerted at its front is lost, as there is no obstacle to sustain it; but on an obstacle moving with the velocity of the wave-front the pressure would vanish, so that this objection does not now hold.

In every such case of an advancing perfect reflector the aggregate amplitude of the superposed incident and reflected wave-trains, of different wave-lengths and periods, will be represented by

$$\xi + \xi' = 2a \sin \frac{mv}{c-v}(x-vt + \frac{mc}{c-v}(x-vt)),$$

thus the appearance presented will be that of a train of waves each of length $(1-v/c)\pi2\lambda/m$, and progressing with the velocity $v$ of the reflector, which travels at one of the nodes of the train. This slowly travelling wave-train corresponds to the stationary train which would be produced by a stationary perfect reflector; but the amplitude is now a varying quantity which, once uniform vibration has been fully established along any path, may itself be described as running on after the manner of a superposed wave-train of very great wave-length $(c/v-1)\pi2\lambda/m$ and of very great velocity $c^2/v$. A somewhat similar state of things arises when a wave-train is incident on a stationary reflector very nearly normally, as may sometimes be seen with incoming rollers along a shelving beach; the visible disturbance at a reflecting ridge, arising from each single wave-crest, then rushes along the ridge at a speed which is at first sight surprising as it is enormously in excess of the speed possible for any simple train of waves travelling into quiescent aether.

3. *Wien’s Law.*—Let us consider a spherical enclosure filled with radiation, and having walls of ideal perfectly reflecting quality so that none of the radiation can escape. If there is no material body inside it, any arbitrarily assigned constitution of this radiation will be permanent. Let us suppose that the radius $a$ of the enclosure is shrinking with extremely small velocity $v$. A ray inside it, incident at angle $\theta$, will always be incident on the walls in its successive refractions at the same angle, except as regards a negligible change due to the motion of the reflector (§ 2) and the length of its path between successive refractions is $2b \cos \theta$. Each undulation on this ray will thus undergo refraction at intervals of time equal to $2a \cos \theta/c$, where $c$ is the velocity of light, and it is easily verified that on each refraction it is shortened by the fraction $2v \cos \theta/c$ or itself: thus in the very long time $T$ required to complete the shrinkage it is shortened by the fraction $\nu T a$, which is $b\delta a /a$ where $b\delta a$ is the total shrinkage in radius, and is independent of the value of $\theta$. The wave-length of each undulation in the radiation inside the enclosure is therefore reduced in the same ratio as the radius. Now suppose that the constitution of the enclosed radiation corresponded initially to a definite temperature. During the shrinkage thermal equilibrium must be maintained among its constituents; otherwise there would be a running down of their energies towards uniformity of temperature, if material radiating bodies are present, which would be superposed on the mechanical operations belonging to the shrinkage, and the process could not be reversible. Such a state of affairs is not possible, for it would land us in processes of the following type. Expand the enclosure, gaining the mechanical work of the radiant pressure against its walls, whatever that may be. Then equalize the intensities of the constituent radiations to those corresponding to a common temperature, by taking advantage of the absorptions of material bodies at the actual temperatures of these radiations; when this is done, as it may actually be to some extent by aid of the sifting produced by partitions which transmit some kinds of radiation more rapidly than others, a further gain of work can be obtained at the expense of the radiant energy. Then contract the remaining radiant energy to its previous volume, which requires an expenditure of less work on the walls of the enclosure than the expansion of the greater amount of radiation originally afforded; and, finally, gain still more work by again equalizing the temperatures of its constituents. The energy now remaining, being of smaller amount and under similar conditions, must have a temperature lower than the initial one. This process might be repeated indefinitely, and would constitute an engine without an extraneous refrigerator, violating Carnot’s principle by deriving an unlimited supply of mechanical work from thermal sources at a uniform temperature.

Thus, independently of any knowledge of the intensity of the mechanical pressure of radiation, or indeed of whether such a pressure exists at all, it is established that the shrinkage of the enclosure must directly transform the contained radiation to the constitution which corresponds to some definite new temperature. Now we have seen that the wave-lengths of its constituents are all reduced in the same ratio by this process. If, then, we can prove that the intensities of these constituents are also all changed in a common ratio by the refractions at the shrinking envelope, it will follow that the distributions of the radiation among the various wave-lengths are, at these two temperatures, and therefore at any two temperatures, homologous, in the sense that the intensity curves, after the wave-lengths in one of them have been reduced in a ratio depending definitely on the two temperatures, differ only in the absolute scale of magnitude of the ordinates.

This procedure modifies Wien’s argument by employing a uniformly shrinking spherical enclosure (cf. Brit. Assoc. Report, 1909). If the enclosure is not spherical, the angles of incidence at successive refractions of the same ray will differ by finite amounts; we must then estimate the average effect of the shrinkage. In the form of enclosure here employed all rays are affected alike, and no averaging is required; while by the principle of Stewart and Kirchhoff what is established for any one form is of general validity.

4. *Pressure of Natural Radiation.*—The question reserved above has now to be settled. At first sight it might have appeared that the reflection is simply total; but, as has been seen in § 2, the advancing perfect reflector does work against the pressure of the radiation, and this work must be changed into radiant energy and thus go to increase the intensity of the reflected ray. Considering electric radiation incident at angle $\theta$, the tangential electric force is annihilated at the reflector; hence the amplitude of the electric vibration is conserved in the reflection, though its phase is reversed. As already seen, the wave-length is shortened approximately by the fraction $2v \cos \theta/c$ in each refraction; thus, just as in § 2, the energy transmitted per unit time per unit area is increased in the same ratio; and allowing for the factor $\cos \theta$ of foreshortening, there is therefore a radiant pressure equal to the total density of radiant energy in front of the reflector multiplied by $\cos \theta$. This argument, being independent of the wave-length, applies to each constituent of the radiation in this direction separately; thus their energies are all increased in the same ratio by the reflection, as was to be proved. When we are dealing with the natural radiation in an enclosure, which is distributed equally in all directions, this factor $\cos \theta$ must be averaged; and we thus attain Boltzmann’s result that the radiant pressure is then one-third of the density of radiant energy in front of the reflector, this statement holding good as regards each constituent of the natural radiation taken separately.

5. *Adiabatic Relations.*—Consider the enclosure filled with radiation of energy-density $E$ at volume $V$, of any given constitution but devoid of special direction, and let it be shrunk to volume $V - 8V$ against its own pressure; if the density thereby become $E + \delta E$, the conservation of the energy requires

$$E V + \delta E V = (E - \delta E)(V - 8V),$$

so that $\delta E V + \delta E V = 0$, or $E$ varies as $V^{-1}$. Again—but now with a restriction to radiation with its energy
RADIATION

distributed as regards wave-length so as to be of uniform temperature—the performance of this mechanical work \( \$E\Delta V \) has changed the energy of radiation \( EV \) from the state that is in equilibrium of absorption and emission with a thermal source at temperature \( T \) to the state in equilibrium with an absorber of some other temperature \( T-\delta T \), and that in a reversible manner; thus by Carnot's principle

\[
\frac{\$E\Delta V}{EV} = - \delta T/T,
\]

so that \( T \) varies as \( V^{-1} \), or inversely as the linear dimensions when the enclosure is shrunk uniformly.

Combining these results, it appears that \( E \) varies as \( T^4 \); this is Stefan's empirical law for the complete radiation corresponding to the temperature, first established on these lines by Boltzmann.

Starting from the principle that this radiation must be a function of the temperature alone, this adiabatic process has in fact given us the form of the function. These results cannot, however, be extended without modification to each separate constituent of the complete radiation, because the shrinkage of the enclosure alters its wave-length and so transforms it into a different constituent.

5. Law of Distribution of Energy.—The effect of compressing the complete radiation is thus to change it to the constitution belonging to a certain higher temperature, by shortening all its wave-lengths by the proportion of one-third of the compression by volume, the temperature being in fact raised by the same proportion; at the same time increasing in a uniform ratio the amounts corresponding to each interval \( \delta \lambda \), so as to get the correct total amount of energy for the new temperature. In the compression each constituent alters so that \( T\lambda \) remains constant, and the energy \( E\delta\lambda \) in the range \( \delta\lambda \) in other respects changes as a function of \( T \) alone. Hence generally \( E\delta\lambda \) must of form \( F(T)/(TX)\delta\lambda \). But for each temperature

\[
T^{-1}F(T)/(TX)\delta\lambda = \alpha \lambda, \quad \alpha \text{ constant},
\]

so that \( T'=\frac{F(T)}{TX} \alpha \lambda T^4 \). Thus, finally, \( F(X)/(X)\delta\lambda \) is of form \( \alpha \lambda'(\lambda)\delta\lambda \), or \( \alpha \lambda^p(\lambda)\delta\lambda \), which is Wien's general formula.

7. Transformation of a Single Constituent.—It is important to follow out this adiabatic process for each separate constituent of the radiation, as a verification, and also in order to ascertain whether anything new is thereby gained.

To this end let now \( \mu(\lambda, T)\delta\lambda \) represent the intensity of the radiation between \( \lambda \) and \( \lambda+\delta\lambda \) which corresponds to the temperature \( T \). The pressure of this radiation, when it is without special direction, is in intensity one-third of this; thus the application of Carnot's principle shows, that before, in adiabatic compression \( T \propto V^{-1} \), so that a small linear shrinkage in the ratio \( r-x \) raises \( T \) in the ratio \( x+1 \). We have still to express the equation of energy. The vibratory energy \( E(\lambda, T)\delta\lambda \). \( V \) in volume \( V \), together with the mechanical work \( \lambda E(\lambda, T)\delta\lambda \), \( 3xV \), yields the vibratory energy

\[
E\lambda(1-x), T(1+x)\delta\lambda(1-x) \cdot V(1-2x),
\]

thus, writing \( E \) and \( \lambda \lambda \) or \( E(\lambda, T) \) we have, neglecting \( x^2 \),

\[
E(1-x) = (E-\lambda E)\delta\lambda + \lambda E d\lambda/dT(1-4x),
\]

so that

\[
5E + \lambda E \delta\lambda - \frac{dE}{dT} = 0,
\]

a partial differential equation of which the integral is

\[
E = \lambda - \phi(\lambda),
\]

the same formula as was before obtained.

This method, treating each constituent of the radiation separately, has in one respect some advantage, in that it is necessary only to postulate an enclosure which totally reflects that constituent, this being a more restricted hypothesis than an absolutely complete reflector.

To determine theoretically the form of the function \( \phi \) we must have some means of transforming one type of radiation into another, different in essence from the adiabatic compression already utilized. The condition that the entropy of the independent radiations in an enclosure is a minimum when they are all transformed to the same temperature with total energy unaltered, is already implicitly fulfilled; it would thus appear that any further advance must involve (§ 11) the dynamics of the radiation and absorption of material bodies.

8. Temperature of an Isolated Ray.—The temperature of each independent constituent of a radiation has here been taken to be a function of the intensity \( E_\lambda \), where \( E_\lambda \delta\lambda \) is the energy per unit volume in the range between wave-lengths \( \lambda \) and \( \lambda+\delta\lambda \); the condition is, however, imposed that this radiation is indifferent as to direction. When a beam of radiation travels without loss in a definite direction across a medium, its form varies as it progresses; but it is reversible inasmuch as it can be turned back at any stage, or concentrated without loss, by perfect reflectors. If the energy of the beam has a temperature, its value must therefore remain constant throughout the progress of the beam, by the principle of Carnot. Now by virtue of a relation in geometrical optics, which on a corpuscular theory would be one aspect of the fundamental dynamical principle of Action, the cross-section \( \delta S \) at any place on the beam, and the conical angle \( \delta \omega \) within which the directions of its rays are there included, are such that the value of \( V^{-1} \delta S \delta \omega \) is conserved along the beam, \( V \) being the velocity of propagation of the undulations.

If we represent the amount of radiant energy transmitted per unit time across the section \( \delta S \) of the beam by \( I\delta S\omega \), it will follow that in passing along the beam its intensity of illumination \( I \) varies as \( V^{-1} \), or as the square of the phase of refraction, provided there is no loss of energy in transmission. This condition requires that changes of index shall be gradual, otherwise there would be loss of energy by partial reflections; in free aether \( I \) is itself constant along the beam.

The volume-density of the energy in any part of the directed beam is \( V^{-1} \delta S \omega \); it is thus inversely as the solid angular concentration of the rays and directly as the cube of the index of refraction. Now we may consider this beam, of aggregate intensity \( I\delta S\omega \), to form an elementary filament of the radiation issuing in the direction of the normal from a perfect radiator.

As such a body absorbs completely and therefore radiates equally in all directions in front of it, the total intensity of radiation from its element of surface \( \delta S \) is \( I \delta S \cos \theta \delta \omega \), or \( \delta S \pi I \), while the volume-density of the total advancing and receding radiation in front of it is \( 2V^{-1} I \delta \omega \), and therefore \( 2T^{-1} V^{-1} \). If we take here \( I \delta S \omega \) to represent the intensity between wave-lengths \( \lambda \) and \( \lambda+\delta\lambda \), this density is the quantity \( E_\lambda \), of which the temperature of the radiator is a function. Thus the quantity \( I \) which optically is a measure of the brightness of the beam, and is conserved along it to the extent that \( \mu I \) is the same from whichever of its cross-sections the beam is supposed to be emitted—also determines its temperature. the latter being that of an enclosure containing undirected radiation of the same range \( \delta\lambda \) which is density \( E_\lambda \delta\lambda \) given by \( E_\lambda = \pi \lambda V^{-1} \mu I \), where \( V \) is the velocity of radiation in the enclosure. When a beam of radiation travels without suffering absorption, its temperature thus continues to be that of its source multiplied by the coefficient of emission of the surface for that kind of radiation, this coefficient being less than unity except in the case of perfect reflectors. The intensity of the beam is by stat. phil. in any part of its path owing to absorption or other irreversible process, this involves a further fall of temperature of the energy of the beam and a rise of entropy which can be completely determined when the relation connecting \( \mu T E \) with \( T \) and \( \lambda \) is known. Any directed quality in radiant energy increases its effective temperature. Splitting a beam into two at a reflecting and refracting surface diminishes the temperature of each part; it is true that if the reflecting surface were molecular the operation could be reversed, but actually the reversed rays would encounter the reflecting molecules in different collocations, and could not (§ 11) recombine into the same detailed phase-relations as before. The direct solar radiation falling on the Earth is almost completely convertible into mechanical effect on account of its very high temperature; there seems ground for believing that certain constituents of it can actually be almost wholly turned to account by the
green leaves of plants. But the same solar radiation, when broken up into diffused sky light, which has no definite direction, has fallen into equilibrium with a much lower temperature, through loss of its reversibility. It has been remarked that the temperatures of the planets can be roughly compared by means of this principle, if their coefficients of absorption of the solar radiation are assumed; that of Neptune comes out below $-200^\circ$ C., if we suppose that it is not kept higher by a supply of internal heat.

To obtain dynamical precision in this discussion an exact definition of the narrow beam such as is usually called a ray is essential. It can be specified as a narrow filament of radiation, such as may be isolated within an infinitely thin, impermeable, bounding tube without thereby producing any disturbance of the motion. If either the tube or the surrounding radiation were not present to keep the beam in shape, it would spread sideways, as in optical diffraction. But the function of the tube is one of pure constraint; thus the change of energy-content of a given length of the tube is represented by energy flowing into it at the end where the radiation enters, and leaving it at the other end, but with no leakage at the sides. The total radiation may be considered as made up of such filaments.

9. Temperature of the Sun.—The mean temperature of the radiating layers of the Sun may be estimated from Stefan's law, by computing the intensity of the radiation at his surface from that terrestrially observed, on the basis of the law of inverse squares; the result is about $6500^\circ$ C. The application of Wien's law, which makes the wave-length of maximum energy vary inversely as the temperature, for the case of a perfectly radiating source, gives a result $5500^\circ$ C. These numbers will naturally differ because (i) the Sun is not a perfect radiator, the constitution of his radiation in fact not following the law of that of a black body, (ii) the various radiating layers have different temperatures, (iii) the radiation may be in part due to chemical and electrical causes, and in so far would not be determined by the temperature alone. The fair agreement of these two estimates indicates, however, that the radiation is largely regulated by the temperature, that the layers from which the main part of it comes are at temperatures not very different, and that not very much of the complete radiation established in these layers and emitted from them is absorbed by the overlying layers.

10. Fluorescence.—When radiation of certain wave-lengths falls upon a fluorescent body, it is largely absorbed, but in such manner as directly to excite other radiation of different type which is emitted in addition to the true temperature-radiation of the body. The distinction involved is that the latter radiation is spontaneously convertible with the heat of the absorbing body at its own temperature, without any external stimulus or compensation; it is, in fact, on the basis of this convertibility that the thermodynamic relations of the temperature-radiation have been established. According to the experimental law of Stokes, the wave-lengths of the fluorescent radiation are longer than those of the radiation which excites it. If the latter radiation were not absorbed in passing into the fluorescent kind, this is what would be expected. For such a spontaneous change must involve loss of availability; and, beyond the wave-length of maximum energy in the spectrum, the temperature of a given density of radiation is greater the shorter its wave-length, as it is a function of that density and the wave-length alone such that greater radiation always corresponds to higher temperature. But it would appear that the opposite should be the case for radiation of long wave-lengths, lying on the other side of the maximum, in which the tendency would thus be for spontaneous change into shorter waves; this may perhaps be related to the fact that the lines of longer wave-lengths in spectra often come out brighter at lower temperatures, for they are then thrown on the other side of the maximum and cannot be thus degraded. The principle does not, however, have free play in the present case, even when the incident radiation is diffused and so has not the abnormally high temperature associated with a directed beam (§ 8), since part of it might be degraded into low-temperature heat, or there might be other compensation of chemical type for any abnormally high availability that might exist in the fluorescent radiation. It has been found that fluorescent radiation, showing a continuous or banded spectrum, can be excited in many gases and vapours; milky phosphorescence of considerable duration, and thus doubtless associated with chemical change, is produced in vacuum tubes, containing oxygen or other complexly constituted gases, by the electric discharge.

11. Entropy of a Ray.—If each definitely constituted beam of radiation has its own temperature and everything is reversible as above, a question arises as to the location of the process of averaging which enters into the idea of temperature. The answer can depend only on the fact, that although the beam is definite as to wave-length and intensity, yet it is far from being a simple wave-train, in that it is constituted of trains of limited lengths and various phases and polarizations, coming from the independent radiating molecules. When such a beam has once emerged, it travels with the speed of light, and can be reflected back intact to its source, and is in so far reversible; but when it has arrived there, the molecules of the source will have changed their positions, and it cannot be wholly reabsorbed in the same manner as it was emitted. There must thus be some feature in the ultimate averaged constitution of the beam, emitted from a body in the definite steady state of internal motion determined by its temperature, which adapts it for spontaneous uncompensated reabsorption into a body at its own (or a lower) temperature, but not at a higher one.

The question of the determination of the form of the function $\phi$ in § 6 would thus appear to be closely connected with the other problems, hitherto imperfectly fathomed, relating to the statistics of kinetic molecular theory. A very interesting attack on the problem from this point of view has recently been made in various forms by Planck. It of course suffices to examine some simple type of radiating system, and the results will be of general validity. He considers an enclosure filled with radiation involving an entirely arbitrary succession of phases and polarizations along each ray, and also containing a system of fixed linear electric oscillators of the Hertzian type, which are taken to represent the transforming action of the radiating and absorbing matter. The radiation contained in the enclosure will be passed through these oscillators over and over again, now absorbed, now radiated, and each constituent will thus settle down in a unilateral or irreversible manner towards some definite intensity and composition. But it does not appear that a system of vibrators of this kind, each with its own period, can perform one of the main functions of a material absorber, namely, the transformation of the relative intensities of the various types of radiation in the enclosure to those corresponding to a common temperature. There would be equilibrium established only between the mean internal vibratory energy in the vibrators of each period and the density of radiation of that period; there is needed also some means of interchanging energy between vibrators of different periods, which probably involves doing away with their exit, or else employing more complex vibrators and assuming a law of distribution of their internal energy. In the absence of any method of introducing this temperature equilibrium directly, Planck originally sought, in the case of each independent constituent, for a function of its intensity of energy and its wave-length, restricted as to form by a certain assumed molecular relation, which has the property of continuously increasing after the manner of entropy, during the progress of that constituent of the radiation in such a system towards its steady state. If the actual entropy $S$ per unit volume could be thus determined, the relation of Clausius $dS=\frac{\Delta U}{T}$ would supply the connexion between the temperature and the density of radiant energy $E$. This procedure led him, in an indirect and tentative manner, to a relation $d\xi/dE^a=-a/\xi$, so that $S=-a\xi\log\xi$, where $a, \beta$ are functions of $\lambda$; an expression which conducts through Clausius' relation to $E=(\beta)^{1-\alpha}$. 

RADIATION
The previous argument then gives \( E(\lambda, T) \propto c_\lambda \lambda^2 e^{-c_\lambda/T} \), a type of formula which was originally suggested by Wien on the basis of the analogy that it assigns the same distribution for the radiant energy, among the various radiations, as for the energy of the molecules in a gas among their various velocities of translation. But the experimental in-

adequacy of this formula afterwards suggested a new pro-

Fers, as *infra*.

Processes may be theoretically assigned for the direct continuous transformation of radiant energy into mechanical energy. Thus we can imagine a radiating body at the centre of a wheel, carrying oblique vanes, which reflect the radiation on the inside of a ring of parallel fixed vanes, which finally reverse its path and return it to the centre. The pressure of the radiation will drive the wheel, and in case its motion is not resisted, a very great velocity may be theoretically assigned to the wheel. The thermodynamic energy of the molecules in such cases lies in the reduction of the effective temperature of the portion of the radiation not thus used up. We might even do away with the radiating body at the centre of the wheel, and consider a beam of definite radiation reflected backwards and forwards across a diameter. It is easy to see that its path will remain diametral; the work done by it in driving the wheel will be concomitant with increase of the wave-length, and therefore with expansion of the length occupied by the beam. The thermodynamic features are thus as those of the case of molecules confined in a cylinder filled with gas, which can change its thermal energy into mechanical energy by expansion of the envelope against mechanical resisting forces. In the case of the expanding gas \( pV = E_0 \), where \( E_0 \) is the total trans-
lational energy of the molecules confined.\textsuperscript{790} Thus the work gained in unlimited expansion, \( p\ell_0 \), is \( E_0 / (\gamma - 1) \).

The final temperature being absolute zero, this should by Carnot's principle be equal to the total initial energy of the gas that is in contact with the radiation and with the whole of the molecules being excluded; when \( \gamma - 1 \) is less than \( \frac{2}{3} \), there is no thermal energy in the molecules in addition to the transitory energy. In the case of the beam of radiation, of length \( l \), between \( n \) and \( n + 1 \) nm reflections, where \( \ell \) is an integer, its total energy \( E \) is, by \( \S \, 2 \), reduced according to the law \( E \sim \ell^{2/3} \).

Thus \( E = \frac{2c_\lambda \ell}{c_\lambda^2 \ell^2} \). When \( \ell \) is small compared with \( c_\lambda \), this gives \( E \approx \frac{2\ell}{c_\lambda^2} \); and when \( \ell \) becomes 2\( \ell \), so that \( p\ell_0 = E \), the temperature of the beam being ultimately reduced to absolute zero by the unlimited expansion. This is in accord with Carnot's principle, in that the whole energy of the beam travelling in a vacuum is mechanically available when reduction to absolute zero of temperature is in our power.

12. Experimental Knowledge.—Under the stimulus of Wien's investigation and of improvements in the construction of linear spectrophotometers and bolometers for the refined measurement of the distribution of energy along a spectrum, the general character of the curve connecting energy and wave-length in the complete radiation at a given temperature has been experimentally ascertained over a wide range. At each temperature there is a wave-length \( \lambda_m \) of maximum radiation, which is displaced towards the ultra-violet, as the temperature rises, and Wien's law of homology (\( \S \, 6 \)) shows that \( \lambda_m T \) should be constant. This deduction, and the law of homology itself, as also the law of Stefan and Boltzmann that the total radiation varies as \( T^4 \), have been closely verified by the experiments of Rubens and Kurlbaum, Lummer and Pringsheim, Paschen and others. They established a steady field of radiation inside a material enclosure by raising the walls to a definite temperature, and measured the intensity of the radiation intensity emitted from it through an opening or slit in the walls, by means of a bolometer or thermo-
pile, this being the radiation of the so-called perfectly black object. The principle here involved formed one of the foundations of Balfour Stewart's early treatment of the theory, and had already been employed by him and Stokes (1865) in experiments on the polarized emission from tourmaline: cf. Stokes, *Math. and Phys. Papers*, iv, 136. It has been remarked by Planck and by Thiesen that the coefficient of \( T^4 \) in Stefan's law, and the value of \( \lambda_m T \), are two absolute physical constants independent of any particular kind of matter, which in conjunction with the constant of gravitation would determine an entirely absolute system of physical units. The form of the function \( \phi(T) \) adopted by Wien and in Planck's earlier discussions, namely, \( G e^{-c/T} \), was found to agree fairly with experiment over the range from 100° C. to 300° C., when \( c = 1.24 \times 10^8 \), and \( c = 1.4435 \) in c.g.s. measure, but not so well when the range is farther extended: it appeared that a larger value of \( c \) was needed to represent the radiation for high values of \( T \), that is, for high temperatures or for very long wave-lengths. Thiesen proposed the somewhat more general form \( G_i(T) e^{-c_i/T} \), and suggested that the value \( k \approx \frac{1}{2} \) agrees better with the experimental numbers than Wien's value \( k = 0 \). Lord Rayleigh was led (Phil. Mag., June 1900) towards this form with \( k = 0 \) to unity from entirely different theoretical considerations, on the assumption of the Maxwell-Boltzmann distribution of the energy of a system, consisting of an isolated block of aether, among its free periods of vibration, infinite in number; in some cases this form appeared as good results as Wien's own.

Acting on a suggestion advanced by Lord Rayleigh, Rubens and Kurlbaum soon afterwards widely extended the test of the formulae by means of the so-called Reststrahlen. A substance such as an aniline dye, which exhibits selective absorption of any group of rays, also powerfully reflects those rays; and Rubens has been able thus to isolate in considerable purity the rays belonging to absorption bands very far down in the invisible ultra-red, having wave-length of order \( 10^{-5} \) cm., which are intensely absorbed by substances such as alizarin, by means of five or six successive reflections of the beam of radiation. By the employment of magnetic and electric fields this radiation, which has wave-lengths of the order of \( +1500° \) C. of the source of radiation, it has been found that the intensity of this definite radiation tends to vary simply as \( T \), with close approximation, thus increasing indefinitely with the temperature, whereas Wien's formula would make it tend to a definite limit. The only existing formula (except the one suggested by Lord Rayleigh) that proved to be in accord with this result was a new one advanced shortly before and supported on theoretical grounds by Planck, namely, \( E_\lambda = C_\lambda^2/\lambda^4 (e^{c_\lambda/T} - 1) \), which for small values of \( T \) agrees with Wien's original form, known to be there satisfactory, while for larger values it tends towards \( C_\lambda^2 \lambda^2 e^{-c_\lambda/T} \); the new formula is, in fact, the simplest and most likely form that satisfies these two conditions.

The point of Lord Rayleigh's argument was that, at any rate at low frequencies, the law of distribution would suggest an equitable partition of the energy between temperature heat and radiant vibrations, and that therefore the energy of the latter should ultimately vary as \( T \); and this prediction, which has thus been verified, may be grafted on to any formula that is in other respects appropriate.

Reconsidering that his previous hypothesis, restricting the nature of the entropy in addition to its property of continually increasing, had thus to be abandoned, Planck had in fact made a fresh start on the basis of a train of ideas which was introduced by Boltzmann in 1877, in order to obtain a precise physical conception of entropy. According to the latter, for an indefinitely numerous system of molecules, with known properties and in given circumstances, there is a definite probability of the occurrence of each statistical distribution of velocities, or say each "complexion" of the system, that is formally possible when all velocities consistent with given total energy are considered to be equally likely as regards each molecule; the distribution of greatest possible probability is the state of thermal equilibrium of the system, and the probability of any other state is a function of the entropy of that state. This conception can be developed only in very simple cases; the application to an ideal monatomic gas-system led Boltzmann to take the entropy proportional to the logarithm of the probability. This logarithmic law is in fact demanded in advance by the principle that the entropy of a system should be the sum of the entropies of its parts, as a matter of a priori considerations of this nature, referring to the distribution of internal vibratory energy among a system of linear electric vibrators of given period, and its equilibrium of exchanges with the surrounding radiant energy. Planck has been guided to an expression for the law of dependence of the entropy of that system on the temperature, which corresponds to the form of the law of radiation above stated. The result gains support from the fact that the expressions for the coefficients to which he is led give determinations of the
absolute physical constants of molecular theory, such as the constant of Avogadro, which are in close accord with other recent determinations. But on the other hand these determinations are already involved in the earlier formula of Rayleigh, which expresses the distribution for long waves, based merely on the Maxwell-Boltzmann principle of the equable partition of the energy among the high free periods belonging to the enclosure which contains it. It is maintained by Jeans that the reason why this principle is of avail only for very long wave-lengths is that a steady state is never reached for the shorter ones, a doctrine which as he admits would entirely remove the foundations of the application of thermodynamic principles to this subject. By an argument based on the theory of dimensions, Lorentz has been led to the conclusion that consistency between temperatures, as measured molecularly, and as measured by the laws of radiation, requires that the ultimate indivisible electric charges or electrons must be the same in all kinds of matter.

The abstract statistical theory of entropy, which is here invoked, admits of generalization in a way which is a modification of that of Planck, itself essentially different from the earlier ideas of Carnot and Clausius. These molecules of matter, whose interactions control physical phenomena, including radiation, are too numerous to be attended to separately in our knowledge. They, and the phenomena in which they interact, must thus be sorted out into differential groups or classes. Elements of energy of specified types might at first sight constitute such classes: but the identity of a portion of energy cannot be traced during its transformations, while an element of physical disturbance can be definitely followed, though its energy changes by interaction with other elements as it proceeds. The whole disturbance may thus be divided into classes, or groups of similar elements, each with permanent existence; and these may be considered as distributed in series of cells, all equivalent in extent, which constitute and map out the material system or other domain of the phenomena. The test of this equivalence of extent is superposition, in the sense that the same element of disturbance always occupies during its wanderings the same number of cells. This framework being granted, the probability of any assigned statistical distribution of the elements of disturbance now admits of calculation; and it represents, as above, the logarithm of the entropy of that distribution, multiplied however by a coefficient which must depend on the minuteness of scale of the statistics. But in the calculation, all the physical laws which impose restrictions on the migrations of the elements of disturbance must be taken into account; it is only after this is done that the rest of the circumstances can be treated as fortuitous. All these physical laws are, however, required and used up in determining the complex of equivalent cells into which the system which forms the seat of the energy is mapped out. On this basis thermodynamics can be constructed in a priori abstract fashion, and with deeper and more complete implications than the formal Carnot principle of negation of perpetual motions can by itself attain to. But the ratio of the magnitude of the temperature and the element of disturbance to the extent of the disturbance itself remains inherent in the results, appearing as an absolute physical constant whose value is determined somehow by the other fundamental physical constants of nature. A prescribed ratio of this kind is, however, a different thing from the hypothesis that energy is constituted atomically, which underlies, as Lorentz pointed out, Planck’s form of the theory. It has indeed already been remarked that the mere fact of the existence of a wave-length $\lambda$, of maximum radiation, whether obeying Wien’s law $\lambda_0T^4 = \text{constant}$ or not, implies by itself some prescribed absolute physical quantity of this kind, whose existence thus cannot be evaded, though we may be at a loss to specify its nature.

13. Modification by a Magnetic Field.—The theory of exchanges of radiation, which makes the equilibrium of radiating bodies depend on temperature alone, requires that, when an element of surface of one body is radiating to an element of surface of another body at the same temperature, the amounts of energy interchanged (when reflection is counted in along with radiation) should be equal. This proposition is a general dynamical consequence—on the basis of the laws of reciprocity developed in this connexion (after W. Rowan Hamilton), independently by Helmholtz, Kirchhoff, and Rayleigh—of the form of the equations of propagation of vibrations in the medium. But in a material medium under the influence of a strong magnetic field these equations are altered by the addition of extraneous terms involving differential coefficients of the third order, and the dynamical consistency of the cardinal principle of the theory of exchanges is no longer thus directly verified. A system of this kind has, in fact, been imagined by Wien in which the principle is imperfectly fulfilled. A beam coming from a body A, and polarized by passage through a nicol, may have its plane of vibration rotated through half a right angle by crossing a magnetically active plate, and may then pass through another nicol, properly oriented for transmission, so as finally to fall on another body B. On the other hand, the radiation from B which gets through this adjacent nicol will have its plane of vibration rotated through another half right angle by the magnetically active plate, and so will not get through the first nicol to the body A. Such possibilities are regarded as the result of an exchange of radiation between A and B and are the result of the want of reversibility of the radiation in the extraneous magnetic field, which might have been expected to lead to proportionate inequalities of concentration; in this example, however, though the defect of reversibility is itself slight, its results appear at first sight to prevent any equilibrium at all. But a closer examination removes this discrepancy. In order to make the system self-contained, reflectors must be added to it, so as to send back into the sources the polarized constituents that are turned aside out of the direct line by the nicols. Then, as Brillouin has pointed out, and as in fact Rayleigh had explained some years before, the radiation from B does ultimately get across to A after passage backward and forward to the reflectors and between the nicols: this, it is true, increases the length of its path, and therefore diminishes the concentration of a single narrow beam, but any large change of path would make the beam too wide for the nicols, and thus require other corrections which may be supposed to compensate. The explanation of the slight difference that is to be anticipated on theoretical grounds might conceivably be that in such a case the magnetic influence, being operative on the phases, alters the statistical constitution of the radiation of given wave-length from the special type that is in equilibrium with a definite temperature, so that after passage through the magnetic medium it is not in a condition to be entirely absorbed at that temperature; there would then be some other element, in addition to temperature, involved in equilibrium in a magnetic field. If this is not so, there must be some thermodynamic compensation involving reaction, extremely small, however, on the magnetizing system.

14. Origin of Spectra.—In addition to the thermal radiations of material substances, those, namely, which establish temperature-equilibrium of the enclosure in which they are confined, there are, however, the extraneous radiations produced by extraneous causes, radiant or electric or chemical. Such radiations are an indication, by the presence of higher wave-lengths than belong in any sensible degree to the temperature, that the steady state has not arrived; they thus fade away, either immediately on the cessation of the exciting cause, or after an interval. The radiations, consisting of definite narrow bright bands in the spectrum, that are characteristic of the gaseous state in which each molecule can vibrate freely by itself, are usually excited by electric or chemical agency; thus there is no ground for assuming that they always constitute true temperature radiation. The absorption of these radiations by strata of the same gases at low temperatures seems to prove that the unaltered molecules themselves possess these free periods, which do not, therefore, belong specially to dissociated ions. Although very difficult to excite directly, these free vibrations are then excited and absorb the energy of the incident waves, under the influence of resonance, which naturally becomes extremely powerful when the tuning is exact; this
RADIATION

indicates, moreover, that the true absorption bands in a gas of sufficiently low density must be extremely narrow. There is direct evidence that many of the more permanent gases do not sensibly emit light on being subjected to high temperature alone, when chemical action is excluded, while others give in these circumstances feeble continuous spectra; in fact, looking at the matter from the other side, the more permanent gases are very transparent to most kinds of radiation, and therefore must be very bad radiators as regards those kinds. The dark radiation of flames has been identified with that belonging to the specific radiation of their gaseous products of combustion. There is thus ground for the view that the impacts of the colliding molecules in a gas, or rather their mutual actions as they swing sharply round each other in their orbits during an encounter, may not be sufficiently violent to excite sensibly the free vibrations of the definite periods belonging to the molecules. But they may produce radiation in other ways. While the velocity of an electron or other electric charge is being altered, it necessarily sends out a stream of radiation. Now the orbital motions of the electrons in an actual molecule must be so adjusted, as appears to be theoretically possible, that it does not emit when its subatomic particles are moving with constant velocity. But in the violent changes of velocity that occur during an encounter this equipoise will be disturbed, and a stream of radiation, without definite periods, but such as might constitute its share of the equilibrium thermal radiation of the substance, may be expected while the encounter lasts. At very high temperatures the energy of this thermal radiation in an enclosure entirely overpowers the kinetic energy of the molecules present, for the former varies as $T^4$, while the latter measures $T$ itself when the number of molecules remains the same. The radiation which can be excited in gases, confined as it is to extremely narrow bands in the spectrum, may indeed be expected to possess such intensity as to be thermally in equilibrium with extremely high temperatures. That the same gases absorb such radiations when comparatively cold and dark does not, of course, affect the case, because emissive and absorptive powers are proportional only for incident radiations of the intensity and type corresponding to the temperature of the body. There is, however, a limit to the radiation which can be excited in a tube of unlimited length which is filled with the gas, then when the temperature has become uniform that gas must send back out of the tube as much radiation as has passed down the tube and been absorbed by it; but if the tube is maintained at a lower temperature, it may return much less. The fact that it is now possible by great optical dispersion to make the line-spectra of prominences in the middle of the Sun's disk stand out bright against the background of the continuous solar spectrum, shows that the intensities of the radiations of these prominences correspond to a much higher temperature than that of the general radiating layer underneath them; their luminosity would thus seem to be due to some cause (electric or chemical) other than mere temperature. On the other hand, the general reversing gaseous layer which originates the dark Fraunhofer lines is at a lower temperature than the radiating layer; it is only when the light from the lower layers is eclipsed that its own direct bright-line spectrum flares out. It is not necessary to attribute this selective flash-spectrum to temperature radiation; it can very well be ascribed to fluorescence stimulated by the intense illumination from beneath. When the radiation in a spectrum is constituted of wide bands it may on these principles be expected to be in equilibrium with a lower temperature than when it is constituted of narrow lines, if the total intensity is the same in the cases compared; this is in keeping with the easier excitation of band spectra (cf. the banded absorption spectra), and with the fact that various gases and vapours do appear to emit band spectra more or less related to the temperature.

15. Constitution of Spectra.—In the problem of the unravelling of the constitutions of the very complex systems of spectral lines belonging to the various kinds of matter, considerable progress has been made in recent years. The beginning of definite knowledge was the discovery of Balmer in 1885, that the frequencies of vibration ($n$) of the hydrogen lines could be represented, very closely and within the limits of error of observation, by the formula $n = \frac{m^2}{n^2}$, when for $m$ is substituted the series of natural numbers 3, 4, 5, ..., 15. Soon afterwards series of related lines were picked out from the spectra of other elements by Liveing and Dewar. Rydberg conducted a systematic investigation on the basis of a modification of Balmer's law for hydrogen, namely, $n = \frac{n}{n^2 - m^2}$. He found that in the group of alkaline metals three series of lines exist, the so-called principal and two subordinate series, whose frequencies fit approximately into this formula, and that similar statements apply to other natural groups of elements; that the constant $N$ is sensibly the same for all series and all substances, while $n$ and $\mu$ have different values for each; and that other approximate numerical relations exist. In each series the lines of high frequency crowd together towards a definite limit on the more refrangible side; near this limit they would, if visible, constitute a band. The principal or strongest series of lines shows reversal very readily. The lines of the first subordinate series are usually the highest, while those of the second subordinate or weakest series are sharp; but with a tendency to broaden towards the less refrangible side. In most series there are, however, not more than six lines visible: helium and hydrogen are exceptions, no fewer than thirty lines of the principal series of the latter having been identified, the higher ones in stellar spectra only. But very remarkable progress has recently been made by R. W. Wood, by exciting fluorescent spectra in a metallic vapour, and also by applying a magnetic field to restore the lines sensitive to the Zeeman effect after the spectrum has been cut off by crossed nicols. The large aggregates of lines thus definitely revealed are also resolved by him into systems in other ways; when the stimulating light is confined to one period, say a single bright line of another substance, the spectrum excited consists of a limited number of lines equidistant in frequency, the interval common to all being presumably the frequency of some intrinsic orbital motion of the molecule. In this way the series belonging to some of the alkali metals have been obtained and several new ones discovered.

Simultaneously with Rydberg, the problem of series was attacked by Kayser and Runge, who, in reducing their extensive standard observations, used the formula $n = \lambda + Bm + Cm^2$, higher terms in this descending series being presumed to be negligible. This cannot be reconciled with Rydberg's form, which gives on expansion terms involving $m^2$; but for the higher values of $m$ the discrepancies rapidly diminish, and do not prevent the picking out of the lines, the frequency-differences between successive lines varying roughly as the inverse squares of the series of natural numbers. For low values of $m$ neither mode of expression is applicable, as was to be expected; and it remains a problem for the future to ascertain if possible the rational formula to which they are approximations. More complex formulas have been suggested by Ritz and others, partly on theoretical grounds.

Considered dynamically, the question is that of the determination of the formula for the disturbed motions of the system which constitutes the molecule. Although we are still far from any definite line of attack, there are various indications that the quest is a practicable one. The lines of each series sort out by aid of the formula above given, have properties in common: they are usually multiple lines, either all doublets in the case of monad elements, or generally triplets in the case of those of higher chemical valency; in very few cases are the lines constituted of single lines. It is found also that the components of all the double or triple lines of a subordinate series are equidistant as regards frequency. In the case of a related group of elements, for example the alkaline metals, it appears that corresponding series are displaced continually towards the less refrangible end as the atomic weight rises; it is found also that the interval in frequency between the double
lines of a series diminishes with the atomic weight, and is proportional to its square. These relations suggest that the atomic weight might here act in part after the manner of a load attached to a fundamental vibrating system, which might conceivably be formed on the same plan for all the members of the group; such a load would depress all the periods, and at the same time it would split them up in the manner above described, if it introduced dissymmetry into the vibrator. The discovery of Zeeman that a magnetic field triples each spectral line, and produces definite polarizations of the three components, in many cases further subdividing each component into lines placed usually all at equal intervals of frequency, is explained, and was in part predicted, by Lorentz on the basis of the electron theory, which finds the origin of radiation in a system of unitary electric charges describing orbits or executing vibrations in the molecule. Although these facts form substantial sign-posts, it has not yet been found possible to assign any likely structure to a vibrating system which would lead to a frequency formula for its free periods of the types given above. Indeed, the view is open that the group of lines constituting a series form a harmonic analysis of a single fundamental vibration not itself harmonic. If that be so, the intensities and other properties of the lines of a series ought all to vary together; it has in fact been found by Preston, and more fully verified by Runge and others, that the lines are multiplied into the same number of constituents in a magnetic field, with intervals in frequency that are the same for all of them. When the series consists of double or triple lines the separate components of the same compound line are not affected similarly, which shows that they are differently constituted. The view has also found support that the different behaviours of the various groups of lines in a spectrum show that they belong to independent vibrators. The form of the vibration sent out from a molecule into the aether depends on the form of the aggregate hodograph of the electronic orbits, which is in keeping with Rayleigh’s remark that the series-laws suggest the kinematic relations of revolving bodies rather than the vibrations of steady dynamical systems.

According to Rydberg, there is ground for the view that a natural group of chemical elements have all the same type of series spectrum, and that the various constants associated with this spectrum change rapidly in the same directions in passing from the elements of one group to the corresponding ones of the following groups, after the manner illustrated in graphical representations of Mendeleeff’s law by means of a continuous wavy curve in which each group of elements lies along this same ascending or descending branch; the chemical elements thus being built up in a series of types or groups, so that the individuals in successive groups correspond one to one in a regular progression, which may be put in evidence by connecting them by transverse curves. Illustrations have been worked out mathematically by J. J. Thomson of the effect of adding successive outer rings of electrons to stable vibrating collocations.

The frequencies of the series of very close lines which constitute a single band in a banded spectrum are connected by a law of quite different type, namely, in the simpler cases \( n^2 = A \cdot B \cdot m^2 \). It may be remarked that this is the kind of relation that would apply to a row of independent similar vibrators in which the neighbours exhibit slight mutual influence of elastic type. If \( \xi \) denote displacement and \( x \) distance along the row, the equation \( \frac{\partial^2 \xi}{\partial t^2} + \xi = k \cdot \xi \) would represent the general features of their vibration, the right-hand side arising from the mutual elastic influences. If the ends of the line of vibrators, of length \( L \), are fixed, or if the vibrators form a ring, the appropriate type of solution is \( \xi = \sin \pi u x \sin \pi u m, \) where \( \mu = \frac{m}{L} \) and \( m \) is integral; further \( - \rho^2 + \frac{n^2}{L^2} = \omega^2 \), hence \( \omega^2 = k^2 - \frac{n^2}{L^2} \cdot \frac{m^2}{\rho^2} \), which is of the type above stated. Dynamical systems of this kind are illustrated by the Lagrangean linear system of connected bodies, such as, for example, a row of masses fixed along a taut cord, and each subject to a restoring elastic force of its own in addition to that of its neighbour. A spectral line might thus be transformed into a band of this type, as the effect of disturbance arising from slight elastic connexions established in the molecule between a system of similar vibrators. But the series in line-spectra are of entirely different constitution; thus for the series expressed by the formula \( \omega^2 = \rho^2 - B \cdot m^2 \) the corresponding period-equation might be expressed in some such form as \( \sin (k^2 - \rho^2) = 2 \cdot \omega^2 \), which belongs to no type of vibrator hitherto analysed.

AUTHORITIES.—The experimental memoirs on the constitution of radiation are mostly in the Annalen der Physik; references are given by Lord Drury, A. Drude, and O. Leipzig, 1900; cf. also reports in the collection issued by the International Congress of Physics, Paris, 1900. See also Lord Rayleigh’s Scientific Papers, in various connections; and Larmor, in Brit. Assoc. Reports, 1900-1902, also the Bakerian Lecture, Roy. Soc. Proc., 1900, for a general discussion of molecular statistical theory in this connexion. Planck’s Theorie der Wärmestrahlung, 1906, gives a discussion from his point of view; there is a summary by Wien in Ency. Math. Wiss,. v. (3) pp. 282-357; also a lecture of H. A. Lorentz to the Math. Congress at Rome, 1908, and papers by J. H. Jeans, Phil. Mag., 1909, on the partition of energy. In spectrum analysis Kayser’s extensive treatise is the standard authority. Winklemann’s Handbuch der Physik, vol. ii. (by Kayser, Drude, &c.), may also be used.

RADICAL (Lat. radix, a root), in English politics, is a term applied to politicians who desire to make thorough, or radical, changes in the constitution and in the social order generally. Although it had been used in a somewhat similar way during the reign of Charles II., the term Radical, in its political sense, originated about the end of the 18th century, probably owing its existence to Charles James Fox, who, in 1779, declared that “radical reform” was necessary. The ideas of the first Radicals were borrowed largely from the authors of the French Revolution. The word was more generally employed during the disturbed period between the close of the Napoleonic wars and the passing of the great Reform Bill of 1832, and was applied to agitators like Henry Hunt and William Cobbett. After the Reform Bill had become law, the advocates of violent change were drawn into the Chartist movement, and the Radicals became less revolutionary both in speech and object. Thus in 1842 an observer writes:—“The term Radical, once employed as a name of reproach, has found its way into high fashion.” And it is not difficult to see why the Radical style in their designation.” About this time many members of Parliament were known as Radicals, among these men being George Grote and Joseph Hume. The Radicals never formed a distinct party in the House of Commons, and subsequently they formed simply the advanced section of the Liberal party. For a few years in the 19th century the wearing of a white hat was looked upon as the distinguishing mark of a Radical, a hat of this colour having been worn by Hunt when addressing meetings.

See W. Harris, History of the Radical Party in Parliament (1885); S. Bamford, Passages in the Life of a Radical (new ed., 1895); C. B. Royallace Kent, The English Radicals; an Historical Sketch (1899).

RADIOACTIVITY. The subject of radioactivity deals with phenomena observable in many substances, and not in bodies of high atomic weight of which uranium, thorium, radium and actinium are the best known examples. These substances possess the property of spontaneously emitting radiations of a special character which are able to penetrate through matter opaque to ordinary light. The beginning of this subject dates from 1896, and was an indirect consequence of the discovery of the X rays made a few months before by Röntgen. It was known that the production of X rays in a vacuum tube was accompanied by a strong phosphorescence of the glass, and it occurred to several investigators that ordinary substances made phosphorescent by visible light might emit a penetrating radiation similar to X rays. Following out this idea, H. Becquerel (1), a distinguished French physicist, exposed amongst other substances a phosphorescent compound of uranium, uranium.

1 These numbers refer to papers noted under References (below).
potassium sulphate, enveloped in paper beneath a photographic plate. A weak photographic effect was obtained. This was shown to be due to a penetrating radiation capable of passing through sheets of matter opaque to ordinary light. Further investigation showed that this photographic action was exhibited by all compounds of uranium and by the metal itself, and had nothing to do with phosphorescence. It was shown equally if the uranium were kept in darkness and did not vary appreciably with time. Becquerel showed that the rays from uranium like X rays were capable of discharging a body whether positively or negatively electrified. A uranium compound brought close to the charged plate of a gold leaf electroscope causes a rapid collapse of the gold leaves. This property of uranium, and also of the radioactive bodies in general, has supplied a delicate and quantitative method of accurate comparison of the intensity of the radiations from substances under varying conditions. A modified form of gold leaf electroscope has come into general use for comparison of the radioactivity of substances. Rutherford (2) made a systematic examination of the discharging effect produced by the rays from uranium and showed that it was due to the production of charged carriers or ions in the volume of the gas through which the radiations pass. In an electric field, the positive ions travel to the negative electrode and vice versa, thus causing a discharge of the electrified body. If a sufficiently strong field is used, the ions are all swept to the electrodes before appreciable loss of their number can occur by recombination. The rate of discharge then reaches a steady maximum value which is not altered by a large increase in voltage. This maximum current through the gas is called the saturation current. The ions produced in gases by the rays from uranium and other radioactive substances are in general identical with those produced by X rays, and the mechanism of conductivity of the gas is very similar in both cases (see CONDUCTION, ELECTRIC: § Through Gases).

Some time after Becquerel's discovery, Mme Curie (3) made a systematic examination of the electric method of a large number of chemical elements and their compounds to test whether they possessed the "radioactive" property of uranium. Only one other element, thorium, was found to show this effect to a degree comparable with that of uranium—a result independently observed by Schmidt. Mme Curie examined the activity of the various compounds of uranium and found that their radioactivity was an atomic property, i.e., the activity was proportional to the amount of the element uranium present, and was independent of its combination with other substances. In testing the activity of the minerals containing uranium, Mme Curie found that the activity was always four to five times as great as that to be expected from their content of uranium. If the radioactivity were an atomic phenomenon, this could only be explained by the presence in these minerals of another substance more active than uranium itself. Relying on this hypothesis, Mme Curie made a chemical examination of uranium minerals in order to try to separate this new radioactive substance. In these experiments, the Austrian Government generously provided Mme Curie with a ton of the residues from the State manufactory of uranium at Joachimsthal, Bohemia. At that place there are extensive deposits of pitchblende or uranite which are mined for the uranium. After separation of the latter, the residues are three to five times as radioactive weight for weight as the uranium. From this residue Mme Curie separated a substance far more radioactive than uranium, which she called polonium in honour of the country of her birth. This substance is usually separated with bismuth in the mineral, but by special methods can be partly separated from it. A further examination revealed the presence of a second radioactive substance which is normally separated with the barium, to which the name "radium" was given. This name was happily chosen, for in the pure state radium bromide has a very great activity—about two million times as great as an equal weight of uranium. By means of successive fractionations of the chloride, the radium was gradually concentrated, until finally the radium was obtained so that the barium lines showed very faintly. The atomic weight was found by Mme Curie to be 226. In a recent redetermination, using a larger quantity of 0.4 grams of pure radium chloride, Mme Curie (4) found the atomic weight to be 226.2. Thorpe (5) using a smaller quantity obtained a value 227. The spectrum of the purified sample of radium chloride obtained by Mme Curie was first examined by Demarçay. It was found to have a characteristic spark spectrum of bright lines analogous in many respects to the spectra of the alkaline earths. Giesel (6) found that pure radium bromide gives a brilliant carmine colour to the bunsen flame. The flame spectrum shows two broad bright bands in the orange-red. There is also a line in the blue-green and two weak lines in the violet. Giesel (7) has taken an active part in the preparation of pure radium compounds, and was the first to place preparations of pure radium bromide on the market. He found that the separation of radium from the barium mixed with it proceeded much more rapidly if the crystallizations were carried out using the bromide instead of the chloride. He states that six to eight crystallizations are sufficient for an almost complete separation. From the chemical point of view radium possesses all the characteristic properties of a new element. It has a definite atomic weight, a well-marked and characteristic spectrum, and distinct chemical properties. Its comparative ease of separation and great activity has attracted much attention to this substance, although we shall see that very similar radioactive properties are possessed by a large number of distinct substances.

Radium emits three distinct types of radiation, known as the α, β, and γ rays, of which an account will be given later. It produces in addition a radioactive emanation or gas which is about 100,000 times as active weight for weight as radium itself. The emanation released from 10 milligrams of pure radium bromide causes a glass tube into which it is introduced to phosphoresce brightly. A brilliant luminosity is produced in phosphorescent substances like zinc sulphide, willemite and barium platino-cyanide when introduced into a tube containing the emanation. The radium emanation, a more detailed account of which will be given later, has proved of the greatest utility in radioactive experiments. The property of radium of producing the emanation has been utilized as a very delicate and certain method, not only of detection but of estimation of small quantities of radium. This "emanation method" depends upon the introduction of the emanation, liberated from a substance by boiling or heating, into a suitable electroscope. The rate of discharge of the electroscope due to the emanation affords a quantitative measure of the amount of radium present. In this way, it is not difficult to determine with certainty the
RADIOACTIVITY

Recently Boltwood (13) has separated another substance from uranium minerals which he has called "ionium." This substance is sometimes separated from the mineral with actinium and has chemical properties very similar to those of thorium. Preparations of ionium have been obtained several thousand times as active as uranium. Ionium emits $\alpha$ rays of short range and has a period of transformation probably much longer than that of radium. Ionium has a special interest inasmuch as it is the substance which changes directly into radium. A preparation of ionium initially free from radium grows radium at a rapid rate. Hofmann found that the lead separated from uranium minerals and named it radiolead. The active constituent in the lead is radium D, which changes into radium E and then into radium F (polonium). Both radium D and radium F are products of the transformation of radium. In addition to these radioactive substances mentioned above, a large number of other radioactive substances have been discovered. Most of these lose their activity in the course of a few hours or days. The properties of these substances and their position in the radioactive series will be discussed later.

Radiations from Radioactive Substances. All the radioactive substances possess in common the property of emitting radiations which darken a photographic plate and cause a discharge of electrified bodies. Very active preparations of radium, actinium and polonium also possess the property of causing strong phosphorescence in some substances. Bodies which phosphoresce under X rays usually do so under the rays from radioactive matter. Barium platinocyanide, the mineral willemite (zinc silicate) and zinc sulphide are the best known examples.

There are in general three types of radiation emitted by the radioactive bodies, called the $\alpha$, $\beta$ and $\gamma$ rays. Rutherford (2) in 1899 showed that the radiation from uranium was complex and consisted of (a) an easily absorbed radiation stopped by a sheet of paper or a few centimetres of air which he called the $\alpha$ rays and (b) a far more penetrating radiation capable of passing through several millimetres of aluminium, called the $\beta$ rays. Later Villard found that radium emitted a very penetrating kind of radiation called the $\gamma$ rays capable of passing before absorption through twenty centimetres of iron and several centimetres of lead.

Giesel and, later, Curie and Becquerel showed that the $\beta$ rays of radium were deflected by a magnetic field. By the work of Becquerel and Kaufmann the $\beta$ rays have been shown to consist of negatively charged particles projected with a velocity approaching that of light, and having the same small mass as the electrons set free in a vacuum tube. In fact the $\beta$ rays are electrons spontaneously ejected from the radioactive matter at a speed on an average much greater than that observed in the electrons set free in a vacuum tube.

The very penetrating $\gamma$ rays are not deflected in a magnetic or electric field and are believed to be of a type of radiation similar to X rays. The $\gamma$ rays are only observed in radioactive substances which emit $\beta$ rays, and the penetrating power of the $\gamma$ rays appears to be connected with the initial velocity of expulsion of the $\beta$ rays. Two general theories have been advanced to account for the properties of these rays. On one view, the $\gamma$ rays are to be regarded as electromagnetic pulses which have their origin in the expulsion of the $\beta$ particle from the atom. On the other hand Bragg has collected evidence in support of the view that the $\gamma$ rays are corpuscular and consist of uncharged particles or "neutral doublets." There is as yet no general consensus of opinion as to the true nature of the $\gamma$ rays.

Rutherford (14) showed in 1903 that the $\alpha$ rays were deflected in a powerful magnetic or electric field. The amount of deflection is very small compared with the $\beta$ rays under similar conditions. The direction of deflection in a magnetic field is opposite to that of the $\beta$ rays, showing that the $\alpha$ rays consist of a stream of positively charged particles. A pencil of rays from a thick layer of radioactive matter is complex and consists of particles moving at varying velocities. If, however,
RADIOACTIVITY

A thin film of radioactive matter of one kind is taken, the particles which escape without absorption are found to be homogeneous and consist of particles projected at an identical speed. Observations of the velocity and mass of the particle have been made by Rutherford. The general method employed for this purpose is similar to that used for the determination of the velocity and mass of the electron in a vacuum tube. The deflection of a pencil of rays in a vacuum is determined for both a magnetic and electric field. From these observations the velocity and value $e/m$ (the ratio of the charge carried by the particle to its mass) are determined. The value of $e/m$ has been found to be the same for the particles from all the types of radioactive matter that have been examined, indicating that the $\alpha$ particles from all radioactive substances are identical in mass. The value of $e/m$ found for the $\alpha$ particle is $5.07 \times 10^6$. Now the value of $e/m$ for the hydrogen atom set free in the electrolysis of water is $6665$. On the assumption that the value of the charge $e$ is the same for the $\alpha$ particle as for the hydrogen atom, the value would indicate that the $\alpha$ particle has about twice the mass of the hydrogen atom, i.e., has the same mass as the hydrogen molecule. If the charge on the $\alpha$ particle is twice that on the hydrogen atom, the value of $e/m$ indicates that the $\alpha$ particle is a helium atom, for the latter has an atomic weight of four times that of hydrogen.

It was difficult at first to decide between these and other hypotheses, but we shall show later that there is now no doubt that the $\alpha$ particle is in reality a helium atom carrying two elementary charges. We may consequently regard the $\alpha$ rays as a stream of helium atoms which are projected from a radioactive substance with a high velocity. The maximum velocity of the $\alpha$ particle from radium is $2 \times 10^6$ cms. per second, or one-fifteenth of the velocity of light. Although the $\alpha$ rays are the least penetrating of the radiations, it will be seen that they play an extremely important part in radioactive phenomena. The velocity of the $\alpha$ particle is not affected by the ionization and heating effects of radioactive matter and are closely connected with the transformations occurring in them.

Under ordinary experimental conditions the greater part of the ionization observed in a gas is due to the $\alpha$ particles. This ionization due to the $\alpha$ rays does not extend in air at atmospheric pressure for more than $7$ cms. from radium, and $8.6$ cms. from thorium. If a screen of aluminium about $0.1$ cm. thick is placed over the active matter, the $\alpha$ rays are completely absorbed, and the ionization above the screen is then due to the $\beta$ and $\gamma$ rays alone. If a layer of lead about $2$ mm. thick is placed over the active matter, the $\beta$ rays are stopped, and the ionization is due almost entirely to the penetrating $\gamma$ rays. By the use of screens of suitable thickness we are thus able to sift out the various types of rays. These three types of radiations all set up secondary radiations in passing through matter. A pencil of $\beta$ rays falling on matter is widely scattered in all directions. This scattered radiation is sometimes called the secondary $\beta$ rays. The $\gamma$ rays give rise to secondary rays which consist in part of scattered $\gamma$ rays and in part electrons moving with a high velocity. These secondary rays in turn produce tertiary rays and so on. The impact of the $\alpha$ rays on matter sets free a number of slow moving electrons which are very easily deflected by a magnetic or electric field. This type of radiation was first observed by J. J. Thomson, and has been called by him the $\delta$ rays.

Emanations or Radioactive Gases.—In addition to their power of emitting penetrating radiations, the substances thorium, actinium and radium possess another very striking and important property. Rutherford (15) in 1906 showed that thorium compounds (especially the oxide) continuously emitted a radioactive emanation or gas. This emanation can be carried away by a current of air and its properties tested apart from the substance which produces it. A little later Dorn showed that radium possesses a similar property, while Giesel and Debiener observed a similar effect with actinium. These emanations all possess the property of ionizing a gas and, if sufficiently intense, of producing marked photographic and phosphorescent action. The activity of the radioactive gases is not permanent but disappears according to a definite law with the time, viz., the activity falls off in a geometric progression with the time. The emanations are distinguished by the different rates at which they lose their activity. The emanation of actinium is very shortlived, the time for the activity to fall to half value, i.e., the period of the emanation, being 3-7 seconds. The period of the thorium emanation is 54 seconds and of the radium emanation 3-9 days. This property of emitting an emanation is shown in a very striking manner by actinium. A compound of actinium is wrapped in a sheet of thin paper and laid on a screen of phosphorescent zinc sulphide. In a dark room the phosphorescence, marked by the characteristic scintillation, is seen to extend on all sides from the active body. A puff of air is seen to remove the emanation and with it the greater part of the phosphorescence.

The emanation of radium is shown to be emitted from the parent matter and escape into the air under some conditions. Rutherford and Soddy (16) showed that under ordinary conditions the temperature of condensation of the radium emanation mixed was $-150^\circ$ C.

The emanations are produced from the parent matter and escape into the air under some conditions. Rutherford and Soddy (17) made a systematic examination of the emanating power of thorium compounds under different conditions. The hydroxide emanates most freely, while in thorium nitrate, practically none of the emanation escapes into the air. Most of the compounds of actinium emanate very freely. Radium compounds, except in very thin films, retain most of the emanation in the compound. The occluded emanation can in all cases be released by solution or by heating. On account of the fact that the period of the emanation of radium can be collected like a gas and stored, when it retains its characteristic properties for a month or more.

Induced Activity.—Curie (18) showed that radium possessed another remarkable property. The surface of any body placed near radium, or still better, immersed in the emanation from it, acquires a new property. The surface after removal is found to be strongly active. Like the emanations, this induced activity in a body decays with the time, though at quite a different rate from the emanation itself. Rutherford (19) independently showed that thorium possessed a like property. He showed that the bodies made active behaved as if a thin film of intensely active matter were deposited on their surface. The active matter could be partly removed by rubbing, and could be dissolved off by strong acids. When the acid was evaporated the active matter remained behind. It was shown that the decay of the activity due to the emanations, and could not be produced if no emanation was present. We shall see that induced activity on bodies is due to a deposit of non-gaseous matter derived from the transformation of the emanations.

Each emanation gives a distinctive active deposit which decays at different rates. The active deposits of radium, thorium and actinium are very complex, and consist of several types of matter. Several hours after removal from the emanation the active deposit from radium decays to half-value—26 minutes, for actinium half-value—34 minutes, for thorium half-value—10-5 hours. The active deposits obtained on a platinum wire or plate are volatilized before a white heat, and are again deposited on the cooler bodies in the neighbourhood. Rutherford showed that the induced activity could be concentrated on the negative electrode in a strong electric field, indicating that the radioactive carriers had a positive charge. The distribution of the active deposit in a gas at low pressure has been investigated in detail by Makower and his colleagues.

Theory of Radioactive Transformations.—We have seen that the radioactive bodies spontaneously and continuously emit a great number of $\alpha$ and $\beta$ particles. In addition, new types of radioactive matter like the emanations and active deposits...
appear, and these are quite distinct in chemical and physical properties from the parent matter. The radiating power is an atomic property, for it is unaffected by combination of the active element with inactive bodies, and is uninfluenced by the most powerful chemical and physical agencies at our command. In order to explain these results, Rutherford and Soddy (20) in 1903 put forward a simple but comprehensive theory. The atoms of radioactive matter are unstable, and each second a definite fraction of the number of atoms present break up with explosive violence, in most cases expelling an α or β particle with great velocity. Taking as a simple illustration that an α particle is expelled during the explosion, the resulting atom has decreased in mass and possesses chemical and physical properties entirely distinct from the parent atom. A new type of matter has thus appeared as a result of the transformation.

The atoms of this new matter are again unstable and break up in turn, the process of successive disintegration of the atom continuing through a number of distinct stages. On this view, a substance like the radium emanation is derived from the transformation of radium. The atoms of the emanation are far more unstable than the atoms of radium, and break up at a much quicker rate. We shall now consider the process of radioactive transformation according to this theory. It is experimentally observed that in all simple radioactive substances, the intensity of the radiation decreases in a geometrical progression with the time, i.e. $I/I_0 = e^{-\lambda t}$, where $I$ is the intensity of the radiation at any time $t$, $I_0$ is the initial intensity, and $\lambda$ is a constant. Now according to this theory, the intensity of the radiation is proportional to the number of atoms breaking up per second. From this it follows that the number of active matter present decreases in a geometrical progression with the time, i.e. $N/N_0 = e^{-\lambda t}$, where $N$ is the number of atoms present at a time $t$, $N_0$ is the initial number, and $\lambda$ the same constant as above. Differentiating, we have $dN/dt = -\lambda N$, i.e. $\lambda$ represents the fraction of the total number of atoms present which break up per second. The radioactive constant $\lambda$ has a definite and characteristic value for each type of matter. Since $\lambda$ is usually a very small fraction, it is convenient to distinguish the products by stating the time required for half the matter to be transformed. This will be called the period of the product, and is numerically equal to $\ln 2/\lambda$. As far as our observation has gone, the law of radioactive change is applicable to all radioactive matter without exception. It appears to be an expression of the law of probability, for the average number breaking up per second is proportional to the number present. Viewed from this point of view, the number of atoms breaking up per second should have a certain average value, but the number from second to second should vary within certain limits according to the theory of probability. The theory of this effect was first put forward by Schweidler, and has since been verified by a number of experimenters, including Kohlrausch, Meyer, and Begener and H. Geiger. This variation in the number of atoms breaking up from moment to moment becomes marked with weak radioactive matter, where only a few atoms break up per second. The variations observed are in good agreement with those to be expected from the theory of probability. This effect does not in any way invalidate the law of radioactive change. On an average the number of atoms of any simple kind of matter breaking up per second is proportional to the number present. We shall now consider how the amount of radioactive matter which is supplied at a constant rate from a source varies with the time. For clearness, we shall take the case of the production of emanation, by radium. The rate of transformation of radium is so slow compared with that of the emanation that we may assume without sensible error that the number of atoms of radium breaking up per second, i.e. the supply of fresh emanation, is on the average constant over the interval required. Suppose that initially radium is completely freed from emanation. In consequence of the steady supply, the amount of emanation present increases, but not at a constant rate, for the emanation is in turn breaking up. Let $g$ be the number of atoms of emanation produced by the radium per second and $N$ the number present after an interval $t$, then $dN/dt = -\lambda N$, where $\lambda$ is the radioactive constant of the emanation. It is obvious that a steady state will be reached when the number of atoms of emanation supplied per second are in the average equal to the atoms which break up per second. If $N_0$ be the maximum number, $q = N_0\lambda$. Integrating the above equation, it follows that $N/N_0 = 1 - e^{-\lambda t}$. If a curve be plotted with $N$ as ordinates and time as abscissae, it is seen that the recovery curve is complementary to the decay curve. The two curves for the radium emanation period, 3-9 days, are shown in fig. 1, the maximum ordinate being in each case $100$.

This process of production and disappearance of active matter holds for all the radioactive bodies. We shall now consider some special cases of the variation of the amount of active matter with time which have proved of great importance in the analysis of radioactive changes.

(a) Suppose that initially the matter $A$ is present, and this changes into $B$ and $B$ into $C$, it is required to find the number of atoms $P$, $Q$ and $R$ of $A$, $B$, and $C$ present at any subsequent time $t$.

Let $\lambda_1$, $\lambda_2$, $\lambda_3$ be the constants of transformation of $A$, $B$, and $C$ respectively. Suppose $n$ be the number of atoms of $A$ initially present. From the law of radioactive change it follows:

$$dQ/dt = \lambda_2 P - \lambda_3 Q,$$

$$dR/dt = \lambda_3 Q - \lambda_3 R.$$

Substituting the value of $P$ in terms of $n$ in (1), $dQ/dt = \lambda_2 n e^{\lambda_2 t} - \lambda_3 Q$;

the solution of which is in the form $Q = n (\lambda_2 e^{\lambda_2 t} - \lambda_3 t)$.

Similarly it can be shown that

$$R = n (\lambda_2 e^{\lambda_2 t} + \lambda_3 e^{-\lambda_3 t} - e^{\lambda_2 t})$$

and

$$P = n (\lambda_2 e^{\lambda_2 t} - \lambda_3 e^{-\lambda_3 t} - e^{\lambda_2 t})$$

where $a$ and $b$ are constants. By substitution it is seen that $a = \lambda_1 (\lambda_3 - \lambda_2)$, and $b = -\lambda_3 (\lambda_2 - \lambda_1)$.

Thus $Q = \frac{n\lambda_1}{\lambda_2 - \lambda_3} (e^{\lambda_2 t} - e^{\lambda_3 t})$.

(b) A primary source supplies the matter $A$ at a constant rate, and the process has continued so long that the amounts of the products $A$, $B$, and $C$ have reached a steady limiting value. The primary source is then suddenly removed. It is required to find the amounts of $A$, $B$, and $C$ remaining at any subsequent time $t$.

In this case the number $n_0$ of particles of $A$ supplied per second from the source is equal to the number of particles which change into $B$ per second, and also of $B$ into $C$. This requires the relation

$$n_0 = \frac{n_0}{\lambda_1} = yQ_0 = \frac{\lambda_3 n_0}{\lambda_1}$$

where $P_0$, $Q_0$, $R_0$ are the initial number of particles of $A$, $B$, $C$ present, and $\lambda_1$, $\lambda_2$, $\lambda_3$ are the constants of transformation.

Using the same quotations as in case (1), but remembering the new initial conditions, it can easily be shown that the number of particles $P$, $Q$, and $R$ of the matter $A$, $B$, and $C$ existing at the time $t$ after removal are given by

$$P = \frac{n_0}{\lambda_1} e^{\lambda_1 t},$$

$$Q = \frac{n_0}{\lambda_1} \left( \frac{\lambda_1}{\lambda_2} e^{\lambda_2 t} - e^{\lambda_3 t} \right),$$

$$R = \frac{n_0}{\lambda_1} \left( e^{\lambda_2 t} + \frac{\lambda_3}{\lambda_2} e^{-\lambda_3 t} - e^{\lambda_2 t} \right),$$

where $a = \frac{(\lambda_1 - \lambda_0)}{(\lambda_1 - \lambda_2)}$, $b = \frac{(\lambda_0 - \lambda_0)}{(\lambda_1 - \lambda_2)}$, $c = \frac{(\lambda_1 - \lambda_1)}{(\lambda_1 - \lambda_2)}$, $d = \frac{(\lambda_0 - \lambda_0)}{(\lambda_1 - \lambda_2)}$.

The curves expressing the rate of variation of $P$, $Q$, $R$ with time are in these cases very different from case (1).

(c) The matter $A$ is supplied at a constant rate from a primary source. Required to find the number of particles of $A$, $B$, and $C$ present at any time $t$ later, when initially $A$, $B$, and $C$ were absent.

This is a converse case from case (2) and the solutions can be obtained from general considerations. Initially suppose $A$, $B$, and $C$ are in equilibrium with the primary source which supplied $A$ at a constant rate. The source of $A$ is then removed and the amounts of $A$, $B$, and $C$ vary according to the equation given in case (2). The source after removal continues to supply $A$ at the same rate as before. Since initially the product $A$ was in equilibrium with the source, and the radioactive processes are in no way changed by the removal of the source, it is clear that the amount of $A$ present in the two parts in which the matter is distributed is unchanged. If $P_1$ be the amount of $A$ produced by the source in the time $t$, and $P_2$...
RADIOACTIVITY

the amount remaining in the part removed, then \( P_1 + P = P_2 \) where \( P_1 \) is the equilibrium value. Thus

\[
P_1/P_2 = 1 - P/P_2.
\]

The ratio \( P_2/P_1 \) can be written down from the solution given in case (2). Similarly the corresponding values of \( Q_1/Q_2, R_1/R_2 \) may be as easily determined. It is observed in these cases that the curves plotted with \( P_2/P_1 \) as ordinates and time as abscissa are complementary to the corresponding curve with \( P_1/P_2 \) as ordinates. This simple relation holds for all recovery and decay curves of radioactive products in general.

We have so far considered the variation in the number of atoms of successive products with time when the periods of the products are known. In practice, the variation of the number of atoms is deduced from measurements of activity, usually made by the electric method. Using the same notation as before, the activity of an \( \alpha \) product is proportional to its rate of breaking up, i.e. to \( \lambda P \) where \( P \) is the number of atoms present. If two products are present, the activity is the sum of two corresponding terms \( \lambda P_1 \) and \( \lambda Q \).

In practice, the activity observed is proportional to \( \lambda P + KQ \). In this way, it is possible to compare the theoretical activity curves of a mixture of products with those deduced experimentally.

Analysis of Radioactive Changes.—The analysis of the successive changes occurring in uranium, thorium, radium and actinium has proved a very difficult matter. In order to establish the existence of a new product and to fix its position in the scheme of changes, it is necessary to show (a) that the new product has a distinctive period of decay and shows some distinctive physical or chemical properties; (b) that the product under consideration arises directly from the product preceding it in the scheme of changes, and is transformed into the product succeeding it.

In general, it has been found that each product shows some distinctive chemical or physical behaviour which allows of its partial or complete separation from a mixture of other products. It must be remembered that in most cases the amount of radioactive matter under examination is too small to detect by weight, but its presence is inferred from its characteristic radiations and rate of change. In some cases, a separation may be effected by ordinary chemical methods; for example thorium X is separated from thorium by precipitation of thorium with ammonia. The Th X remains in the filtrate and is practically free from thorium. In other cases, a separation is effected by a separation of a metal in the solution of active matter. For example, polonium (radium F) always comes down with bismuth and may be separated by placing a bismuth plate in a solution. Radium C is separated from radium B by adding nickel filings to a solution of the two. Radium C is deposited on the nickel. In other cases, a partial separation may be effected by electrolysis or by differences in volatility when heated. For example, when radium A, B and C are deposited on a platinum plate, on heating the plate, radium B is volatilized and is deposited on any cold surface in the neighbourhhood. A very striking method of separating certain products has been recently observed depending upon the recoil of an atom which breaks up with the expulsion of an \( \alpha \) particle. The residual atom acquires sufficient velocity in consequence of the ejection of an \( \alpha \) particle to escape and be deposited on bodies in the neighbourhhood. This is especially marked in a low vacuum. This property was independently investigated by Russ and Makower (21) and by Hahn (22).

The latter has shown that by means of the recoil, actinium C may be obtained pure from the active deposit containing actinium A, B and C, for B emits \( \alpha \) rays, and actinium C is driven from the plate by the recoil. In a similar way a new product, thorium D, has been isolated. By the recoil method, radium B may be separated from radium A and C. The recoil method is one of the most definite and certain methods of settling whether an \( \alpha \) ray product is simple or complex.

We have already pointed out that with the emission of an \( \alpha \) or \( \beta \) particle, some products have been observed which do not emit any characteristic radiation and have been called "rayless products." For example, radium D and thorium A are changing substances which break up without emitting either penetrating \( \alpha \) or \( \beta \) rays. They appear to emit slow \( \beta \) rays which can only be detected by special methods.

The presence and properties of a rayless product can be easily inferred if it is transformed into a product emitting a radiation, for the variation in activity of the latter affords a method of determining the amount of the parent product present. The distinction between a "ray" and a "rayless" product is not clear. It may be that the atom of a rayless product undergoes a rearrangement of its constituent parts giving rise to an atom of the same mass but of different properties. In the case of an \( \alpha \) ray or \( \beta \) ray product, the expulsion of an \( \alpha \) or \( \beta \) particle affords an obvious explanation of the appearance of a new product with distinctive physical properties.

In the table a list of the known products of transformation is given. In each case, the half period of transformation is given and the type of radiation emitted. If the product emits \( \alpha \) rays, the range of ionization of the \( \alpha \) particle in air is given.

</table>

In each of the groups under the heading uranium, thorium and actinium, each product is derived from the direct transformation of the product above it.

**Products of Radium.**—Radium is transformed directly into the emanation which in turn goes through a rapid series of transformations called radium A, B and C. The complete analysis of these changes has involved a large amount of work. The emanation changes first into radium A, a substance of period 3 minutes emitting only \( \alpha \) rays. Radium A changes into radium B, a product of period 26 minutes emitting \( \beta \) rays of penetrating power small compared with those emitted from the next product radium C. The product radium C has proved of considerable importance, for it not only emits very penetrating \( \alpha \) rays and \( \beta \) rays, but is the origin of the \( \gamma \) rays arising from radium in equilibrium. When a wire charged negatively has been exposed for some time in the presence of the radium emanation, it becomes coated with an invisible film of radium A, B and C. After
removal from the emanation for 20 minutes, radium A has practically disappeared and the α rays arise entirely from radium C. Radium C has proved very valuable in radioactive measurements as providing an intense source of homogeneous α rays. Twenty-four hours after removal, the activity due to radium B and C has become exceedingly small. The wire, however, still shows a very small residual activity, first noted by Mme Curie. This residual activity measured by the α rays rapidly increases with the time and reaches a maximum in about three years. The active deposit of slow change has been examined in detail by Rutherford (23) and by Meyer and Schweidler (24). It has been shown to consist of three successive products called radium D, E and F. Radium D is a rayless substance of slow period of transformation. Its period has been calculated by Rutherford to be about 40 years, and by Meyer and Schweidler about 12 years. Antonoff (25) fixes the period of about 17 years. Radium D changes into E, a β ray product of period about 5 days, and E into F, an α ray product of period 140 days. It was at first thought that radium E was complex, but no evidence of this has been observed by Antonoff. The product radium F is of special interest, for it is identical with polonium—the first active body separated by Mme Curie. In a similar way it has been shown that radium D is the primary source of the activity observed in lead or "radiolead" separated by Hofmann. It is interesting to note what valuable results have been obtained from an examination of the minute residual activity observed on bodies exposed in the presence of the radium emanation.

Radio Emulsion.—The radium emanation is to be regarded as a typical radioactive product or transition element which exists in a gaseous form. It is produced from radium at a constant rate, and is transformed into radium A and helium. Its half-period of transformation is 3-86 days. The emanation from radium has been purified by condensing it in liquid air, and pumping out the residual gases. The volume (26) of the emanation at normal pressure and temperature to be derived from one gram of radium in equilibrium is about 0.6 cubic millimetres. This small quantity of gas contains initially more than three-quarters of the total activity of the radium before its separation. In a pure state, the emanation is 100,000 times as active weight for weight as pure radium. Pure emanation in a spectrum tube gives a characteristic spectrum of bright lines (27). The discharge in the gas is bluish in colour. With continued sparking, the emanation is driven into the walls of the tube and the electrodes. Notwithstanding the minute volume of emanation available, the boiling-point of the emanation has been determined at various pressures. At atmospheric pressure Rutherford (28) found the boiling-point to be that of helium, which has been shown to be 66.6° C, and Gray and Ramsay (29) 71.0° C. Liquid emanation appears colourless when first condensed; when the temperature is lowered, the liquid emanation freezes, and at the temperature of liquid air glows with a bright rose colour. The density of liquid emanation has been estimated at 5 or 6.

Approximate estimates of the molecular weight of the radium emanation were early made by diffusion methods. The molecular weight in most cases came out about 100. In a comparison by Perkins of the rate of diffusion of the emanation with that of a monatomic vapour of high molecular weight, viz. mercury, the value deduced was 234. Since the radium atom in breaking up gives rise to one atom of the emanation and one atom of helium, its atomic weight should be 226—4 = 222.

The emanation appears to have no definite chemical properties, and in this respect belongs to the group of inert monatomic gases. Two of the commonest examples are helium and argon. It is partially soluble in water, and readily absorbed by charcoal.

Thorium.—The first product observed in thorium was the emanation. This gives rise to the active deposit which has been analysed by Rutherford, Miss Brooks and by Hahn, and shown to consist of probably four products—thorium A, B, C and D. Thorium A is a rayless product of period 10-5 hours; thorium B an α ray product of period about one hour. The presence of thorium C has been inferred from the two types of α rays present in the active deposit, but no chemical separation of B and C has yet been found possible. Hahn has shown that thorium D—a β ray product of period 3 minutes—can easily be separated by the recoil method. A special interest attaches to the product thorium X (30), which was first separated by Rutherford and Soddy, since experiments with this substance laid the foundation of the general theory of radioactive transformations. A close analysis of thorium has led to the separation of a number of new products. Hahn (31) found that a very active substance emitting α rays, which give rise to thorium X, could be separated from thorium minerals. This active substance, called radiothorium, has been closely examined by Hahn and Blanc. Its period of decay was found by Hahn to be about 2 years, and by Blanc to be 737 days. From an examination of the activity of commercial thorium nitrate of different ages, Hahn showed that another product must be present, which he called mesothorium. This is separated from thorium with Th X by precipitation with ammonia. Thorium is first transformed into the rayless product mesothorium, of period about 5 years. This gives rise to a β ray product of quick transformation, which in turn changes into radiothorium. This changes into thorium X, and so on through a long series of changes. When isolated in the pure state, radiothorium would have an activity about a thousand times greater than radium, but would lose its activity with time with a period of about 2 years. Mesothorium, when first separated, would be inactive, but in consequence of the production of radiothorium, its activity would rapidly increase for several years. After reaching a maximum, it would finally decay with a period of five years. Since a large amount of thorium is separated annually from thorium minerals, it would be of great importance at the same time to separate the radiothorium and mesothorium present. For many purposes active preparations of these substances would be as valuable as radium itself, and the amount of active matter from this source would be greater than that at present available from the separation of radium from uranium minerals.

Actinium.—The transformations observed in actinium are very analogous to those in thorium. Actinium itself is a rayless product which changes into radioactinium, an α ray product of period 10-5 days, first separated by Hahn (32). This changes into actinium X, of period 10-2 days, first separated by Godlewski (33). Actinium X is transformed into the emanation which in turn gives rise to three further products, called actinium A, B and C. Although very active preparations of actinium have been prepared, it has so far not been found possible to separate the actinium from the rare earths with which it is mixed. We do not in consequence know its atomic weight or spectrum.

Origin of Radium.—According to the transformation theory, radium, like all other radioactive products, must be regarded as a changing element. Preliminary calculations showed that radium must have a period of transformation of several thousand years. Consequently in order that any radium could exist in old minerals, the supply must be kept up by the transformation of some other substance. Since radium is always found associated with uranium minerals, it seemed probable from the beginning that uranium must be the primary element from which radium is derived. If this were the case, in old minerals which have not been altered by the action of percolating waters, the ratio of the amount of radium to uranium in a mineral must be a constant. This must evidently be the case, for in a state of equilibrium the rate of breaking up of radium must equal the rate of supply of radium from uranium. If R, P be the number of atoms of uranium and radium respectively in equilibrium, and λ₁, λ₂ their constants of change, then

\[ \lambda_1 R = \lambda_2 P / Q \]

where \( T_1 \) and \( T_2 \) are the half-periods of transformation of uranium and radium respectively. The work of Boltwood (34), Strutt (35) and McCoy (36) has conclusively shown that the ratio of radium to uranium in old minerals is a constant. Boltwood and Strutt determined the quantity of radium present in a mineral by the emanation method, and the amount of uranium by analysis.
RADIOACTIVITY

In order, however, to obtain a direct proof of the genetic relation between uranium and radium, it is necessary to show that radium appears after some time in a uranium compound from which all trace of radium has been initially removed. It can readily be calculated that the growth of radium should be easily observed by the emanation method in the course of one week, using a kilogram of uranium nitrate. Experiments of this kind were first made by Soddy (37), but initially no definite evidence was obtained that radium grew in the solution at all. The rate of production of radium, if it took place at all, was certainly less than 1 in 20,000 of the amount to be expected if uranium were transformed directly into radium. It thus appeared probable that one or more products of slow period of transformation existed between uranium and radium. Since uranium must be transformed through these intermediate stages before radium appears, it is evident that the initial rate of production of radium under these conditions might be extremely small. This conclusion has been confirmed by Soddy, who has shown that radium does appear in the solution which has been placed aside for several years.

Since the direct parent of radium must be present in radioactive minerals, one of the constituents separated from the mineral must grow radium. This was shown to be the case by Boltwood (38), who found that actinium preparations produced radium at a fairly rapid rate. By the work of Rutherford and Boltwood, it was found that the growth of radium was due to actinium itself, but to a new substance separated in some cases with the actinium. This new substance, which emits a rays, was separated by Boltwood (38), and called by him “ionium.” It has chemical properties very similar to thorium.

Soddy has shown that the period of ionium is probably not less than 20,000 years, indicating that ionium must exist in uranium minerals in not less than ten times the quantity of radium. It has not yet been directly shown that uranium produces ionium, but there can be no doubt that it does so.

Since ionium produces radium, Boltwood (38) has determined by direct experiment that radium is half transformed in 2000 years—a number in good agreement with other data on that subject. The constant relation between uranium and radium will only hold for old minerals where there has been no opportunity for chemical alteration or removal of its constituents by the action of percolating water or other agencies. It is quite possible that altered minerals of no great age will not show this constant relation. It seems probable that this is the explanation of some results of Mlle. Gleditsch, where the relation between uranium and radium has been found not to be constant for some mineral specimens.

Connection of the Radioelements.—We have already seen that a number of slowly transforming radioactive substances, viz. polonium (radium F), radiolead (radium D) and ionium are linked up to the uranium-radium series of transformations. Boltwood (39) has made a systematic examination of the relative activity in the form of very thin films due to each of the products present in the uranium-radium family. The results are shown in the following table, where the activity of pure uranium itself is taken as unity.

Taking into account the differences in the ionization due to an a particle from the various products, the results indicate that uranium expels two a particles for one from each of the other a ray products in the series of transformations. This indicates either that two particles are expelled during the transformation of the atom of uranium, or that another a ray product is present which has so far not been separated from the uranium.

Although thorium is nearly always present in old uranium minerals and uranium in thorium minerals, there does not appear to be any radioactive connexion between these two elements. Uranium and thorium are to be regarded as two distinct radioactive elements. With regard to actinium, there is still no definite information of its place in the scheme of transformations. Boltwood has shown that the amount of actinium in uranium minerals is proportional to the content of uranium. This indicates that actinium, like radium, is in genetic connexion with uranium. On the other hand, the activity of actinium with its series of a ray products is less than that of radium itself or uranium. In order to explain this anomaly, Rutherford has suggested that at a certain stage of disintegration the uranium-radium series, the disintegration is complex, and two distinct kinds of matter appear, one in much larger quantity than the other. On this view, the smaller fraction is actinium, so that the latter is a branch descendant of the main uranium-radium series.

End Products of Transformation.—It is now definitely established that the a particle expelled from any type of radioactive matter is an atom of helium, so that helium is a necessary accompaniment of radioactive changes involving the expulsion of a particles. After the radioactive transformations have come to an end, each of the elements uranium and thorium and actinium should give rise to an end or final product, which may be either a known element or some unknown element of very slow period of transformation. Supposing, as seems probable, that the expulsion of an a particle lowers the atomic weight of an element by four units—the atomic weight of helium—the atomic weights of each of the products in the uranium and radium series can be simply calculated. Since uranium expels two a particles, the atomic weight of the next ray product, ionium, is 238-5 or 230-5. The atomic weight of radium comes out to be 266-5, a number in good agreement with the experimental value. Similarly the atomic weight of polonium is 210-5, and that of the final product after the transformation of polonium should be 206-5. This value is very close to the atomic weight of lead, and indicates that this substance is the final product of the transformation of radium.

This suggestion was first put forward by Boltwood (40), who has collected a large amount of evidence bearing on this subject. Since in old minerals the transformations have been in progress for periods of time, in some cases measured by hundreds of millions of years, it is obvious that the end product, if a stable element, should be an invariable companion of the radioelement and be present in considerable quantity. Boltwood has shown that lead always occurs in radioactive minerals, and in many cases in amount about that to be expected from their uranium content and age. It is difficult to settle definitely this very important problem until it can be experimentally shown that radium is transformed into lead, or, what should prove simpler in practice, that polonium changes into helium and lead. Unfortunately for a solution of this problem within a reasonable time, a very large quantity of polonium would be necessary. Mme. Curie and Debierne have obtained a very active preparation of polonium containing about 5th milligram of pure polonium. Rutherford and Boltwood and Curie and Debierne have both independently shown that polonium produces helium as a result to be expected, since it emits a particles.

Production of Helium.—In 1902 Rutherford and Soddy suggested that the helium which is invariably found in radioactive minerals was derived from the disintegration of radioactive matter. In 1903 Ramsay and Soddy definitely showed that helium was produced by radium and also by its emanation. From the observed mass of the a particle, it seemed probable from the first that the a particle was an atom of helium. This conclusion was confirmed by the work of Rutherford and Geiger (41), who showed that the a particle was an atom of helium carrying two unit charges of electricity. In order to prove definitely this relation, it was necessary to show that the a particles, quite independently of the active matter from which they were expelled, gave rise to helium. This was done by Rutherford and Royds (42), who showed that the a particles from a large quantity of emanation to be fired through the
very thin glass walls of the containing tube. The collected particle gave the spectrum of helium, showing, without doubt, that the α particle must be a helium atom.

Since the α particle is an atom of helium, all radioactive matter which expels α particles must give rise to helium. In agreement with this, Debye and Giesel have shown that actinium as well as radium produces helium. Observations of the production of helium by radium have been made by Ramsay and Soddy, Curie and Dewar, Hirnstedt and others. The rate of production of helium per gram of radium was first definitely measured by Dewar (43). His preliminary measurements gave a value of 134 cubic mms. of helium per year per gram of radium and its products. Later observations extending over a larger interval give a rate of production about 168 cubic mms. per year. As a result of preliminary measurements, Boltwood and Rutherford (44) have found a growth of 163 cubic mms. per year. It is of interest to note that the rate of production of helium by radium is in excellent agreement with the value calculated theoretically. From their work of counting the particles and measuring their charge, Rutherford and Geiger showed that the rate of production of helium should be 178 cubic mms. per year.

Properties of the α Rays.—We have seen that the rays are positively charged atoms of helium projected at a high velocity, which are capable of penetrating through thin metal sheets and several centimetres of air. Early observations indicated that the ionization due to a layer of radioactive matter decreased approximately according to an exponential law with the thickness of the absorbing matter placed over the active matter. The true nature of the absorption of the α rays was first shown by Bragg and by Bragg and Kleeman (45). The active particles projected from a thin film of active matter of one kind have identical velocities, and are able to ionize the air for a definite distance, termed the “range” of the α particle. It was found that the ionization per centimetre of path due to a narrow pencil of α rays increases with the distance from the active matter, at first slowly, then more rapidly, near the end of the range. After passing through a maximum value the ionization falls off rapidly to zero. The range of an α particle in air has a definite value which can be accurately measured. If a uniform screen of matter is placed in the path of the pencil of rays the range is reduced by a definite amount proportional to the thickness of the screen. All the α particles have their velocity reduced by the same amount in their passage through the screen. The ranges in air of the α rays from the various products of the radioelements have been measured. The ranges for the different products vary between 2-8 and 8-6 mms.

Bragg has shown that the range of an α particle in different elements is nearly proportional to the square roots of their atomic weights. Using the photographic method, Rutherford (46) showed that the velocity V of an α particle of range R cms. in air is given by \( V^2 = K(R + 1:25) \), where K is a constant. In his experiments he was unable to detect particles which had a velocity lower than \( 8:8 \times 10^4 \) cms. per second. Geiger (47), using the scintillation method, has recently found that α particles of still lower velocity can be detected under suitable conditions by the scintillations produced on a zinc sulphide screen. He has found that the connexion between velocity and range can be closely expressed by \( V^2 = KR \), where K is a constant.

On account of the great energy of motion of the α particle, it was at first thought that it pursued a rectilinear path in the gas without appreciable deflection due to its encounters with the molecules. Geiger (48) has, however, shown by the scintillation method that the α particles are scattered to a marked extent in passing through matter. The scattering increases with the atomic weight of the substance traversed, and becomes more marked with decreasing velocity of the α particle. A small fraction of the α particles falling on a thick screen are deflected through more than a right angle, and emerge again on the side of incidence.

Rutherford and Geiger (49) have devised an electrical method of counting the α particles expelled from radioactive matter. The α particle enters through a small opening into a metal tube containing a gas at a reduced pressure. The ionization produced by the α particle in its passage through the gas is magnified several thousand times by the movement of the ions in a strong electric field. In this way, the entrance of an α particle into the detecting vessel is shown by a sudden and large deflection of the measuring instrument. By this method, they determined that \( 3.4 \times 10^6 \) α particles are ejected per second from one gram of radium itself and from each of its α ray products in equilibrium with it. By measuring the charge on a counted number of α particles, it was found that the α particle carries a positive charge of \( 0.3 \times 10^{-9} \) electrostatic units. From other evidence, it is known that this must be twice the fundamental unit of charge carried by the hydrogen atom. It follows that this unit charge is \( 4.65 \times 10^{-10} \) units. This value is in good agreement with numerous recent determinations of this fundamental quantity by other methods. With this data, it is possible to calculate directly the values of some important radioactive data. The calculated and observed values are given below:

<table>
<thead>
<tr>
<th>Characteristic</th>
<th>Calculated</th>
<th>Observed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Volume of the emanation in cubic millimetres per gram of radium</td>
<td>585</td>
<td>585</td>
</tr>
<tr>
<td>Volume of helium in cubic millimetres produced per year per gram of radium</td>
<td>158</td>
<td>169</td>

</tbody>
</table>

The calculated values are in all cases in good agreement with the experimental numbers.

It is well known from the experiments of Sir William Crookes (50) that the α rays produce visible scintillations when they fall on a screen of phosphorescent zinc sulphide. This is shown in the instrument called the spintharoscope. By means of a suitable microscope, the number of these scintillations on a given area in a given time can be counted. The number so obtained is practically identical with the number of α particles incident on the screen, determined by the electrical method of counting. This shows that each α particle produces a visible flash of light when it falls on a suitable zinc sulphide screen.

The scintillations produced by α rays are observed in certain diamonds, and their number has been counted by Regener (51) and the charge on each particle has been deduced. The latter was the first to employ the scintillation method for actual counting of α particles. Kimura has shown that the number of α particles can also be counted by the photographic method, and that each particle must produce a detectable effect.

Absorption of β Rays.—We have seen that the β particles, which are emitted from a number of radioactive products, carry a negative charge and have the same small mass as the particles constituting the cathode rays. The velocity of expulsion and penetrating power of the β rays varies widely for different products. For example, the rays from radium B are very easily absorbed, while some of the rays from radium C are of a very penetrating type. It has been found that for a single β ray product, the particles are absorbed according to an exponential law with the thickness of matter traversed, and Hahn has made use of this fact to isolate a number of new products. It has been generally assumed that the exponential law of absorption is a criterion that the β rays are all expelled at the same speed. In addition, it has been supposed that the β particles do not decrease much in velocity in passing through matter. Wilson has recently made experiments upon homogenous β rays, and finds that the intensity of the radiation falls off in some cases according to a linear rather than to an exponential law, and that there is undoubtedly evidence that the β particles decrease in velocity in traversing matter. Experiments upon the absorption of β rays are greatly complicated by the scattering of the β rays in their encounters with the molecules. For example, if a pencil of β rays falls on a metal, a large fraction of the rays are scattered...
sufficiently to emerge on the side of incidence. This scattering of the β rays has been investigated by Eve, McLennan, Schmidt, Crowther and others. It has been found that the scattering for different chemically connected with the atomic weight and position in the periodic table. McCland and Schmidt have given theories to account for the absorption of the β rays by matter. The whole problem of absorption and scattering of particles by substances is very complicated, and the question is still under active examination and discussion.

The negative charge carried by the β rays has been measured by a number of observers. It has been shown by Rutherford and Makower that the number of β particles expelled per second from one gram of radium in equilibrium is about that to be expected if each atom of the β ray products in breaking up emits one β particle.

Heat Emission of Radioactive Matter.—In 1903 it was shown by Curie and Laborde (52) that a radium compound was always hotter than the surrounding medium, and radiated heat at a constant rate of about 100 gram calories per hour per gram of radium. The rate of evolution of heat by radium has been measured subsequently by a number of observers. The latest and most accurate determination by Schweidler and Hess, using about half a gram of radium, gave 118 gram calories per gram per hour (53). There is now no doubt that the evolution of heat by radium and other radioactive matter is mainly a secondary phenomenon, resulting mainly from the expulsion of a particles. Since the latter have a large kinetic energy and are easily absorbed by matter, all of these particles are stopped in the radium itself or in the envelope surrounding it, and their energy of motion is transformed into heat. On this view, the evolution of heat from any type of radioactive matter is proportional to the kinetic energy of the expelled a particles. The view that the heating effect of radium was a measure of the kinetic energy of the a particles was strongly confirmed by the experiments of Rutherford and Barnes (54). They showed that the emanation and its products when removed from radium were responsible for about three-quarters of the heating effect of radium in equilibrium. The heating effect of the radium emanation decayed at the same rate as its activity. In addition, it was found that the ray products, viz. the emanation radium A and radium C, each gave a heating effect approximately proportional to their activity. Measurements have been made on the heating effect of uranium and thorium and of pitchblende and polonium. In each case, the evolution of heat has been shown to be approximately a measure of the kinetic energy of the a particles.

In experiments of the evolution of heat from radium and its emanation have brought to light the enormous amount of energy accompanying the transformation of radioactive matter where a particles are emitted. For example, the emanation from one gram of radium in equilibrium with its products emits heat initially at the rate of about 90 gram calories per hour. The total heat emitted during its transformation is about 12,000 gram calories. Now the initial volume of the emanation from one gram of radium is 6 cubic millimetres. Consequently one cubic centimetre of emanation during its life emits 2 × 109 gram calories. Taking the atomic weight of the emanation as 222, one gram of the emanation emits during its 2 × 109 gram calories of heat. This evolution of heat is enormous compared with that emitted in any known chemical reaction. There is every reason to believe that the total emission of energy from any type of radioactive matter during its transformation is of the same order of magnitude as for the emanation. The atoms of matter must consequently be regarded as containing enormous stores of energy which are only released by the dis-integration of the atom.

A large amount of work has been done in measuring the amount of the thorium and radium emanation in the atmosphere, and in determining the quantity of radium and thorium distributed on the surface of the earth. The information already obtained has an important bearing on geology and atmospheric electricity.

Makower, Radioactive Substance, 1908; J. Joly, Radioactivity and Geology, 1909. See also Annual Report of the Chemical Society. (E. R.)

RADIOLARIA, so called by H. Haeckel in 1866 (Polycystina, by C. G. Ehrenberg, 1838), the name given to Marine Sarcodina, in which the cytoplasmic body gives off numerous fine radiating pseudopods (rarely amastosing) from its surface, and is provided with a chitinous “central capsule,” surrounding the inner part which encloses the nucleus, the inner and outer cytoplasmic communication through either one or three apertures or numerous pores in the capsule. The extracapsular cytoplasm is largely transformed into a gelatinous substance (“calymma”), through which a granular network of plasma passes to form a continuous layer bearing the pseudopods at the surface; this gelatinous layer is full of large vacuoles, “alveoli,” as in other pelagic Sarcodina (Heliozoa, &c.), Glogiberinidae, &c., among Foraminifera (g.v.). The protoplasm may contain oil-globules, pigment-grains, reserve-grains and crystals. There is frequently a skeleton present, either of silica (pure or containing a certain amount of organic admixture), or of “acinanth” (possibly a proteid, allied to vitellin, but regarded by W. Schewiakoff as a hydrated silicate of calcium and aluminium); never calcareous or arenaceous. The skeleton may consist of spicules, isolated or more or less compacted, or form a laminated shell, which, in correlation with the greater resistance of its substance, is of lighter and more elegant structure than in the Foraminifera. The alveoli contain a liquid which, as shown by Brandt, is rich in carbon dioxide, and in proportion to its abundance may become much lighter than sea-water; and possibly the gelatinous substance of the calymma is also lighter than the medium. In Acantharia the protoplasm at the base
of the projecting spines is often differentiated into a bundle of fibres converging on to the spines some way up (distally); these, comparable to the myonemes of Infusoria (q.v.), &c., and termed "myophrìsa", possibly serve to drag outwards the surface and so extend it, with concurrent dilatation of the alveoli, and lower the specific gravity of the animal. In this group also a thick temporary flagellum "sarcocystallum" may be formed, apparently by the coalescence of a number of pseudopodia. The pigmented mass or "phaeodium" in the ectoplasm of Phaeodaria appears to be an excretory product, formed within the central capsule and passing immediately outwards; a similar uniform deposit of pigmented granules occurs in the Colloïd species, *Thalassiosira nucleiata*. The wall of the central capsule is simple in the Spumellaria, but formed of two layers in the Nassellaria and Phaeodaria. In the Nassellaria the oscule is simply a perforated area, and a cone of differentiated fibres in the intracapsular cytoplasm has its base on it; it is termed the "porocorne," and the fibres may possibly be muscular (myonemes). In Phaeodaria, the inner membrane at each oscule is prolonged through the outer into a tube ("proboscis"); the outer membrane of the principal oscule forms a large radially striated circular plate, the "astypyle," or "operculum." The innermost shell of some with concentric shells may lie within the central capsule, or even within the nucleus; this is due to the growth of these organs after the initial shell is formed, so that they pass out by lobes through the latticed openings of the embryonic shell, which lobes ultimately coalesce outside the embryonic chamber, and so come finally to invest it (fig. 11. 17). In some, a symbiosis occurs with *Zooxanthella*, Brande, a Flagellate of the group Chrysomadinaeae, which in the resting state inhabits the extracapsular cytoplasm growing and dividing freely therein, and only (under study) becoming free and flagellate on the death of the host (fig. 111. 4, 6-13). The Silicoflagellata or Dictyochidae, also possessing a vegetable colouring matter, but with a skeleton of impure silica (like that of Phaeodaria), may pass some of their lives in symbiosis with Radiolaria.

Living Radiolaria were first observed and partially described by W. J. Tilesius in 1833-5 and 1834, by W. Baird in 1835, and by C. G. Ehrenberg in 1831, as luminous organisms in the sea; F. J. Meyen in 1834 recognized their animal character and the siliceous nature of their spicules. Ehrenberg a little later described a large number of Nassellarian skeletons under the name of Polycystina (1838), but without more than a very slight knowledge of a few living forms. T. H. Huxley in 1851 made the first adequate study of the living animal, and was followed by J. Müller in the same decade. E. Haeckel began his publications in 1862, and in two enormous, abundantly illustrated, systematic works, besides minor publications, has dealt exhaustively with the cytology, classification, and distribution of the class. Next in value come the contributions of Richard Hertwig (largely developmental), besides those of L. Cienkowski, Karl Brandt and A. Borgert, while to F. Dreyer and V. Hécker we owe valuable studies on the physical relations of the skeleton.

Our classification is taken from Haeckel.

A. *Spumellaria*, Haeck. (*Peripylea*, Hertwig). Central capsule perforated with numerous evenly distributed pores. Skeleton siliceous, latticed or of detached spicules, or absent. Form homaxonic or with at least three planes of symmetry intersecting at right angles, rarely irregular or spiral, sometimes forming colonies, *i.e.* with several central capsules in a common external cytoplasm.

**Fig. I.** — *Thalassiosira pelagicæ*, Haeckel; × 45. CK, central capsule; EP, extracapsular protoplasm; al, alveoli; liquid-holding vacuoles in the protoplasm similar to those of *Heliozoa*, Hastigerina, &c.; ps, pseudopodia. The minute unlettered dots are the "yellow cells."

**Fig. II.** — *Eucryptium cranioides*, Haeckel; × 150; one of the Nassellaria. Entire animal as seen in the living condition. The central capsule is hidden by the beeche-shaped siliceous shell within which it is lodged.

I. Skeleton of detached spicules, or absent.

Fam. 1. **Colloidea.** Skeleton absent. *Thalassiosira*, Huxl. (figs. 1. and 11. 1); *Thalassophyra*, Haeck.; *Collozoaum*, Haeck. (fig. 111. 2-5, 15, 16); *Actissa*, Haeck.

II. *Skeleton latticed or spongy-reticulate.*

Fam. 3. **Sphaeroidea.** Skeleton homaxonic, sometimes colonial. *Collophera*, Mull.; *Haliomma*, Ehrl.; *Actinomma*, Haeck. (fig. 111. 17), showing concentric latticed shells, the smallest intranuclear, all connected by radial spines; *Spongiosphaeræ*, Haeck. (fig. iv. 8); *Heliosphaeræ*, Haeck. (fig. 111. 14).

Fam. 4. **Prunioidea.** Skeleton a prolate spheroid or cylinder of circular section, sometimes constructed like a dice-box.

Fam. 5. **Discoidæ.** Shell flattened, of circular plan, rarely becoming spiral.

Fam. 6. **Larcoidea.** Shell with three unequal axes, elliptical in the plane of any two, more rarely becoming irregular or spiral.

B. *Acantharia*, Haeck. (*Actinozoea*, Hertw.). Skeleton of spicules of acanthin radiating from a centre, and usually twenty.
disposed on five successive zones of four on alternating meridians, the zones corresponding to equator, tropics, and circumpolar circles on the globe; pores of central capsule in scattered groups.

Fam. 1. Actinelida. Spines numerous, more than twenty, irregularly grouped. Litholophus, Haeck.; Xiphacantha, Haeck.

Fam. 2. Acanthonida. Spines twenty, simple, usually equal. Acanthometra, J. Müller (fig. iv. 6, 7); Asterometra, Haeck.; Amphionide, Haeck. (fig. iii. 18).

Fam. 3. Sphaerophractida. Spines equal, branching and often coalescing into a latticed shell, homaxonic.

Fam. 4. Phanophractida. Branching spines coalescing into a latticed shell which is elongated and elliptical in at least one plane.

C. Nassellaria, Haeck. (Monopylea, Hertw.). Silico-skeletal Radiolaria in which the central capsule is typically monaxon (cone-shaped), with a single perforate area (porta-plate) placed on the back of the cone; the membrane of the capsule, the nucleus single; the skeleton is extracapsular and forms a scaffold-like or bee-hive-like structure of monaxon form, a tripod or calath, a sagittal ring, or a combination of these.

Fam. 2. Plectida, Haeck. Skeleton formed of a single branching spine, a tripod or usually a 4-radiate calath, its branches sometimes reticulate. Genera: Plagiocantha, Haeck.; Plegmatium, Haeck.

Fam. 3. Syrroidea. Shell latticed around the sagittal ring ("cephalia"), sometimes with a lower chamber added.

Fam. 5. Cystoidea, Haeck. Skeleton a monaxon or triradiate shell, or continuous piece (beehive-shaped). Genera: Halcaecida, Haeck.; Eucyrtidium, Haeck. (fig. ii.); Carpocanum, Haeck. (fig. iv. 3).

Fam. 6. Stephioida, Haeck. Skeleton a sagittal ring continuous with the branched spines, and sometimes growing out into other rings or branches. Genera: Acanthodesma, Haeck.; Zygophyllum, Haeck.; Lithocircus, Haeck. (fig. iv. 1).

D. Phaeodaria, Haeck. (Trigylaea, Hertw.). Radiolaria of cruciate symmetry, prolonged into tubular processes with three oscula to the central capsule, one inferior, the principal, and two symmetrically placed on either side of the opposite pole; skeleton of spicules, a network of hollow filaments or a minutely alveolate shell, of a combination of silica with organic substance; extracapsular protoplasm containing in front of the large oscule an agglomeration of dusky purplish or greenish pigment ("phaeodarium").

Fam. 2. Phaeosophrida. Spicules united into a latticed shell. Genera: Aulophaera, Haeck. (fig. iv. 9); Auloplagia, Haeck.; Connochaeta, Haeck.

Fam. 3. Phaeogromida, Haeck. Shell continuous, traversed by fine canals or finely alveolate, provided with at least one pyle. Genera: Challengeria, Wyv., Thomson.; Lithogromia, Haeck.

Fam. 4. Phaeoconchi. Shell as in Phaeosophrila, but of two symmetrical halves (valves), which meet in the plane of the three oscula ("frontal of Haeckel), who term the plane of symmetry through the shells "sagittal"). Genera: Conchitium, Haeck.; Coelodendrum, Haeck. (fig. iv. 4).

The following passages may be repeated here from Sir E. Ray Lankester's article "Protozoa" in the 9th edition of this Encyclopaedia:

The important differences in the structure of the central capsule of different Radiolaria were first shown by Hertwig, who also discovered that the spines of the Acanthometrid skeleton, although of silica but of an organic compound (but see above). In view of this latter fact and of the peculiar numerical and architectural features of the Acanthometrid skeleton, it seems proper to separate them altogether from the other Radiolaria. The Peripylea may be regarded as the starting-point of the Radiolarian pedigree, and have given rise on the one hand to the Acanthometrida, which

---

**Fig. III.**—Radiolaria. 1. Central capsule of _Thalassocalypta nuclei_, Huxley, in radial section. a, the large nucleus (Binnenbläschen); b, corpuscular structures of the intracapsular protoplasm containing concretions; c, wall of the capsule (membranous shell), showing the fine radial pore-canals; d, nuclear fibres (chromatin substance) of the nucleus. 2, 3. _Collosoiretum inermis_, J. Müller, two different forms of colonies, of the natural size. 4. Central capsule from a colony of _Collosoiretum inermis_, showing the intracapsular protoplasm and nucleus, broken up into a number of spores, the germ of swarm-spores or flagellule; each encloses a crystalline rod. c, yellow cells lying in the extracapsular protoplasm. 5. A small colony of _Collosoiretum inermis_, magnified 25 diameters. a, alveoli (vacuoles) of the extracapsular protoplasm; b, central capsule, each containing besides protoplasm a large oil-globule. 6-13. Yellow cells of various Radiolaria: 6, normal yellow cell; 7, 8, division with formation of transverse septum; 9, a modified condition according to Brandt; 10, division of a yellow cell into four; 11, ameboid condition of a yellow cell from the body of a dead Sphaerocodium; 12, a similar cell in process of division; 13, a yellow cell the protoplasm of which is creeping out of its cellulose envelope. 14, _Sphaerodinium inermis_, Haeck., living example; o, nucleus; b, central capsule; c, silicious basket-work skeleton. 15. Two swarm-spores (flagellulae) of _Collosoiretum inermis_, set free.
from such a central capsule as that drawn in 4; each contains a crystal $b$ and a nucleus $a$. 16. Two swarm-spores of *Colo-
zoom inermes*, of the second kind, viz. devoid of crystals, and of two sizes, a macropore and a micropore. They have been set free from central capsules with contents of a different appearance from that drawn in 4. $a$, nucleus. 17. *Actinomma aster-
canthion*, Haeck.: one of the Peripylea. Entire animal in optical section. $a$, nucleus; $b$, wall of the central capsule; $c$, innermost silicious shell enclosed in the nucleus. $\theta$, middle shell lying within the central capsule; $\theta'$, outer shell lying in the extracapsular protoplasm. Four radial silicious spines holding the three spherical shells together are seen. The radial fibril-
lation of the protoplasm and the fine extracapsular pseudopodia are to be noted. 18. *Amphionece messanensis*, Haeck.: one of the Acanthometridae. Entire animal as seen living.

of the protoplasmic body. $a$, the tri-lobed nucleus; $b$, the silicious shell; $c$, oil-globules; $d$, the perforate area (plate-
port) of the central capsule. 4. *Coelodendrum gracilissimum*, Haeck.: living animal, complete; one of the Tripylae. $a$, the character-
istic dark pigment (phaeodium) surrounding the central capsule $b$. The peculiar branched silicious skeleton, consisting of hollow fibres, and the expanded pseudopodia are seen. 5. Central capsule of one of the Tripylae, isolated, showing $a$, the nucleus; $b$, $c$, the inner and the outer laminae of the capsule wall; $d$, the chief or polar aperture; $e$, the two secondary apertures. 6, 7. *Acanthometra claspereti*, Haeck. 7. shows the animal in optical section, so as to exhibit the characteristic meeting of the spines at the central point as in all Acanthometridae; 6 shows the transition from the uninuclear to the multinuclear condition by the breaking up of the large nucleus. $a$, small nucleus; $b$, large fragments of the single nucleus; $c$, wall of the central capsule; $d$, extracapsular jelly (not protoplasm); $e$, peculiar intracapsular yellow streptocysts. 8. *Spongophora* striapunctata, Haeck.: one of the Peripylea. Silicious skeleton not quite completely drawn on the right side: $a$, the spherical extracapsular shell (compare fig. iii. 17), supporting very large radial spines which are connected by a spongy network of silicious fibres. 9. *Aul-
sphaera elegantisissima*, Haeck.: one of the Phaeodaria. Half of the silicious skeleton.

"The occasional total absence of any silicious or acanthinous skeleton does not appear to be a matter of classifier importance, since skeletal elements occur in close allies of those very few forms which are totally devoid of skeleton. Similarly it does not appear to be a matter of great significance that some forms (Polycyttaria) form colonies, instead of the central capsules separating from one another after fission has occurred."

"It is important to note that the skeleton of silices or acanthin does not correspond to the shell of other Sarcodina, which appears rather to be represented by the membranous central capsule. The skeleton does, however, appear to correspond to the spines of Heliozoa, and there is an undeniable affinity between such a term as Clathrulina and the Sphaerid Peripylea (such as Heliosphaera, fig. iii. 14). The Radiolaria are, however, a very strongly marked group, definitely separated from all other Sarcodina by the membranous central capsule sunk in their protoplasm. Their differences inter se do not affect their essential structure. The variations in the chemical composition of the skeleton and in the perfora-
tion of the capsule do not appear superficially. The most obvious features in which they differ from one another relate to the form and complexity of the skeleton, a part of the organism so little characteristic of the group that it may be wanting altogether. It is not known how far the form-species and form-genera which have been distinguished in such profusion by Haeckel as a result of the study of the skeletons are permanent (i.e. relatively permanent) physiological species. There is no doubt that very many are local and conditionally varieties, or even merely stages of growth, of a single Protistan species. The same remark applies to the species determined among the shell-bearing Reticularia. It must not be supposed, however, that less importance is to be attached to the distinguishing and recording of such forms because we are not able to assert that they are permanent species."

"The streaming of the granules of the protoplasm has been observed in the pseudopodia of Radiolaria as in those of Heliozoa and Reticularia; it has also been seen in the deeper protoplasm; and granules have been definitely seen to pass through the pores of the central capsule from the extracapsular to the extracapsular pro-
toplasm. A feeble vibrating movement of the pseudopodia has been occasionally noticed."

"The production of swarm-spores has been observed in Acanthometridae and in the Polycyttaria and Thalas-siicolidae, and only in the two latter groups have any detailed observations been made. Two distinct processes of swarm-spore production have been observed by Cienkowski, confirmed by Haeckel, distinguished by the character of the resulting spores, which are called 'crystalligous' and 'isospores' (fig. iii. 15) in the one case, and 'dimorphous' or 'anisospores' in the other (fig. iii. 16). In both processes the nucleated protoplasm within the central capsule breaks up by a more or less regular cell-division into small

![Fig. IV.—Radiolaria. 1. Lithocirrus annularis, Hertwig; one of the Monopylaea. Whole animal in the living state (optical section): $a$, nucleus; $b$, wall of the central capsule; $c$, yellow cells; $d$, perforated area of the central capsule (Monopylaea). 2. Cystidium inermes, Hertwig; one of the Monopylaea. Living animal. An example of a Monopylaean destitute of skeleton. $a$, nucleus; $b$, capsule-wall; $c$, yellow cells in the extracapsular protoplasm. 3. Carpocanium diadema, Haeck.: optical section of the beehive-shaped shell to show the form and position

of the protoplasmic body. $a$, the tri-lobed nucleus; $b$, the silicious shell; $c$, oil-globules; $d$, the perforate area (plate-port) of the central capsule. 4. Coelodendrum gracilissimum, Haeck.: living animal, complete; one of the Tripylae. $a$, the character-
istic dark pigment (phaeodium) surrounding the central capsule $b$. The peculiar branched silicious skeleton, consisting of hollow fibres, and the expanded pseudopodia are seen. 5. Central capsule of one of the Tripylae, isolated, showing $a$, the nucleus; $b$, $c$, the inner and the outer laminae of the capsule wall; $d$, the chief or polar aperture; $e$, the two secondary apertures. 6, 7. Acanthometra claspereti, Haeck. 7. shows the animal in optical section, so as to exhibit the characteristic meeting of the spines at the central point as in all Acanthometridae; 6 shows the transition from the uninuclear to the multinuclear condition by the breaking up of the large nucleus. $a$, small nucleus; $b$, large fragments of the single nucleus; $c$, wall of the central capsule; $d$, extracapsular jelly (not protoplasm); $e$, peculiar intracapsular yellow streptocysts. 8. Spongophora striapunctata, Haeck.: one of the Peripylea. Silicious skeleton not quite completely drawn on the right side: $a$, the spherical extracapsular shell (compare fig. iii. 17), supporting very large radial spines which are connected by a spongy network of silicious fibres. 9. Aul-
sphaera elegantisissima, Haeck.: one of the Phaeodaria. Half of the silicious skeleton."

pieces, the details of the process differing a little in the two cases. In those individuals which produce crystalliferous swarm-spores, each spore encloses a small crystal (fig. 111.15). On the other hand, in those individuals which produce dimorphous swarm-spores, the contents of the capsule (which in both instances is a set of natural rupture) are seen to consist of individuals of two sizes, 'megaspores' and 'microspores,' neither of which contain crystals (fig. 111.16). The further development of the spores has not been observed in either case. Both process have been observed in the same species, and it is suggested that there is an alternation of sexual and asexual generations, the crystalliferous spores developing directly into adults, which in turn produce in their central cavity 'megaspore-swarm-spores' and 'microspore-swarm-spores' which in a manner analogous to that observed in the Volvocinean Flagellata copulate (permanently fuse) with one another (the larger with the smaller) before proceeding to develop. The adults resulting from this process will, it is suggested, produce in their turn crystalliferous swarm-spores. Unfortunately we have no observations to support this hypothetical scheme of a life-history.

"Fusion or conjugation of adult Radiolarians, whether preliminary to swarm-spore-production or independently of it, has not been observed—this affording a distinction between them and Heliozoa."

Simple fission of the central capsule of adult individuals, preceded of course by nuclear fission, and subsequently of the whole protoplasmic mass, has been observed in several genera of Acantharia and Phaeolaria, and is probably a general method of reproduction in the group. In Spumellaria it gives rise to colonial 'Polyctytarian' forms when the extracapsular protoplasm does not divide.

The siliceous shells of the Radiolarians are found abundantly in certain rocks from Palaeozoic times onwards. They furnish, together with Diatoms and Sponge spicules, the silica which has been segregated as flint in the Chalk formation. They are present in large numbers (as much as 10%) in the Atlantic ooze, and in the celebrated 'Barbados earth' (a Tertiary deposit) are the chief components.

Bibliography.—The most important systematic works are those of Dujardin (1842-52) and of Richardson (1862-66) on the Radiolarians. The "Challenger" Expedition (vol. xvii., 1887), which contains full lists of the older literature. Among the most important recent studies we cite K. Brandt, "Die Koloniebildenden Radiolarien" in Fauna and Flora des Golfes von Neapel, xii. (1885); A. P. de Loriol, "Les Radiolaires," Annales de la Société Zoologique de France, xii. (1889); F. Dreyer in Jenaischer Zeitschr., xix. (1892); V. Häcker in Zeitsch. f. Wiss. Zool., xiii. (1903).

RADIOMETER. It has been remarked at various times, amongst others by Fresnel, that bodies delicately suspended within a partial vacuum are subject to apparent repulsion by radiation. The question was definitely investigated by Sir W. Crookes, who had found that some delicate weighings in vacuo were vitiated by this cause. It appeared that a surface blackened so as to absorb the radiant energy directed on it was repelled relatively to a polished surface. He constructed an apparatus in illustration, which he called a radiometer or light-mill, by pivoting a vertical axle carrying equidistant vertical vanes inside an exhausted glass bulb, one side of each vane being blackened and the other side bright, the blackened sides all pointing the same way round the axle. When the rays of the sun or a candle, or dark radiation from a warm body, are incident on the vanes, the dark side of each vane is repelled more than the bright side, and thus the vanes are set into rotation with accelerated speed, which becomes uniform when the forces produced by the radiation are balanced by the force of the resistance of the air in the walls of the bulb. The name radiometer arose from an idea that the final steady speed of rotation might be utilized as a rough measure of the intensity of the exciting radiation.

The problem of the cause of these striking and novel phenomena at first produced considerable perplexity. A preliminary question was whether the mechanical impulsion was a direct effect of the light, or whether the radiation only set up internal stresses, acting in and through the residual air, between the vanes and the walls of the enclosure. The answer to this was found experimentally by Arthur Schuster, who suspended the whole instrument in delicate equilibrium, and observed the effect of introducing the radiation. If the light exerted direct impulsion on the vanes, their motion would gradually drag the case round after them, by reason of the friction of the residual air in the bulb and of the pivot. On the other hand, if the effects arose from balanced stresses set up inside the globe by the radiation, the effects on the vanes and on the case would be of the nature of action and reaction, so that the establishment of motion of the vanes in one direction would involve impulsion of the case in the opposite direction; but when the motion became steady there would no longer be any torque either on the vanes or on the case, and the latter would therefore come back to its previous position of equilibrium; finally, when the light was turned off, the decay of the motion of the vanes would involve impulsion of the case in the direction of their motion until the moment of the restoring torque arising from the suspension of the case had absorbed the angular momentum in the system. Experiment showed that the latter prediction was what happened. The important part played by the residual air in the globe had also been deduced by Osborne Reynolds from observing that on turning off the light, the vanes came to rest very much sooner than the friction of the pivot alone would account for; in fact, the rapid subidence is an illustration of Maxwell's great theoretical discovery that viscosity in a gas (as also diffusion both of heat and of matter generally) is sensibly independent of pressure.

Some phenomena of retardation in the production of the effect had led Sir G. G. Stokes and Sir W. Crookes to the same general conclusion.

The origin of these phenomena was recognized, among the first by O. Reynolds, and by P. G. Tait and J. Dewar, as a consequence of the kinetic theory of the constitution of gaseous media. The temperature of a gas is measured by the mean energy of translation of its molecules, which are independent of each other except during the brief intervals of collision; and collision of the separate molecules with the blackened surface of a vane, warmed by the radiation, imparts heat to them, so that they rebound from it with greater velocity than they approached. This increase of velocity implies an increase of the reaction on the surface, the black side of a vane being thus pressed with greater force than the bright side. In air of considerable density the mean free path of a molecule, between its collisions with other molecules, is exceedingly small; but for any such increase of gaseous pressure in front of the black surface would be immediately neutralized by flow of the gas from places of high to places of low pressure. But at high exhaustions the free path becomes comparable with the dimensions of the glass bulb, and this equalization proceeds slowly. The general nature of the phenomena is thus easily understood; but it is at a maximum at pressures comparable with a milli- metre of mercury, at which the free path is still small, the greater number of molecules operating in intensifying the result. The problem of the stresses in rarefied gaseous media arising from inequalities of temperature, which is thereby opened out, involves some of the most delicate considerations in molecular physics. It remains practically as it was left in 1879 by two memoirs communicated to the Phil. Trans. by Osborne Reynolds and by Clerk Maxwell. The method of the latter investigator was purely a priori. He assumed that the distribution of molecules and of their velocities, at each point, was slightly modified, from the exponential law belonging to a uniform condition, by the gradient of temperature in the gas (S. Devrisson). This produced an inequality which he expressed by a set of equilibrium under a modified internal pressure equal in all directions. If, therefore, the walls of the enclosure held...
RADISH—RADIUM 807

the gas that is directly in contact with them, this equilibrium would be the actual state of affairs; and it would follow from the principle of Archimedes that, when extraneous forces such as gravity are not considered, the gas would exert no resultant force on any body immersed in it. On this ground Maxwell inferred that the forces acting in the radiometer are connected with gliding of the gas along the unequally heated boundaries; and as the laws of this slipping, as well as the constitution of the adjacent layer, are uncertain, the problem becomes very intricate. Such slipping had shown itself at high exhaustions in the experiments of A. A. Kundt and E. G. Warburg in 1875 on the viscosity of gases; its effects would be corrected for, in general, by a slight effective addition to the thickness of the gaseous layer.

Reynolds, in his investigation, introducing no new form of law of distribution of velocities, uses a linear quantity, proportional to the mean free path of the gaseous molecules, which he takes to represent (somewhat roughly) the average distance from which molecules directly affect by their revolution, the state of the medium; the gas not being uniform on account of the gradient of temperature, the change going on at each point is calculated from the elements contributed by the parts at this particular distance in all directions. He lays stress on the dimensional relations of the problem, pointing out that the phenomena which occur with large vanes in highly rarefied gas could also occur with proportionally smaller vanes in gas at higher pressure. The results coincide with Maxwell's so far as above stated, though the numerical coefficients do not agree. According to Maxwell, priority in showing the necessity for slipping over the boundary rests with Reynolds, who also discovered the cognate fact of thermal transpiration, meaning thereby that gas travels up the gradient of temperature in a capillary tube, owing to surface-actions, until it establishes such a gradient of pressure (extremely minute) as will prevent further flow. In later memoirs Reynolds followed up this subject by proceeding to establish definitions of the velocity and the momentum and the energy at an element of volume of the molecular medium, with the precision necessary in order that the dynamical equations of the medium in bulk, based in the usual manner on these quantities alone, without directly considering thermal stresses, shall be strictly valid—a discussion in which the relation of ordinary molar mechanics to the more complete molecular theory is involved.

Of late years the peculiarities of the radiometer at higher gas-pressure have been very completely studied by E. F. Nichols and G. F. Hull, with the result that there is a certain pressure at which the molecular effect of the gas on a pair of nearly vertical vanes is balanced by that of convection currents in it. By thus controlling and partially eliminating the aggregate gas-effect, they succeeded in making a small radiometer, horizontally suspended, into a delicate and reliable measurer of the intensity of the radiation incident on it. With the experience thus gained in manipulating the vacuum, the achievement of thoroughly verifying the pressure of radiation on both opaque and transparent bodies, in accordance with Clerk Maxwell's formula, has been effected (Physical Review, 1901, and later papers) by E. F. Nichols and G. F. Hull; some months earlier Lebédew had published in the Annalen der Physik a verification for metallic vanes so thin as to avoid the gas-action, by preventing the production of sensible difference of temperature between the two faces by the incident radiation. (See RADIATION.)

More recently J. H. Poynting has separated the two effects experimentally on the principle that the radiometer pressure acts along the normal, while the radiation pressure acts along the ray which may be directed obliquely. (J. L.*).

RADISH, Raphanus sativus (nat. order Cruciferae), in botany, a fleshy-rooted annual, unknown in the wild state. Some varieties of the wild radish, R. Raphanistrum, however, met with on the Mediterranean coasts, come so near to it as to suggest that it may possibly be a cultivated race of the same species. It is very popular as a raw salad. There are two principal forms, the spindle-rooted and the turnip-rooted.

The radish succeeds in any well-worked not too heavy garden soil, but requires a warm, sheltered situation. The seed is generally sown broadcast, in beds 4 to 5 ft. wide, with alleys between, the beds requiring to be netted over to protect them from birds. The earliest crop may be sown about the middle of December, the seed-bed being at once covered with litter, which should not be removed till the plants come up, and then only in the daytime, and when there is no frost. If the crop succeeds, which depends on the state of the weather, it will be in use about the beginning of March. Another sowing may be made in January, a third early in February, if the season is a favourable one, and still another towards the end of February, from which time till October a small sowing should be made every fortnight or three weeks in spring, and rather more frequently during summer. About the end of October, and again in November, a late sowing may be made on a south border or where the plants are being protected in severe weather with litter or mats. To winter radishes, which grow to a large size, should be sown in the beginning of July and in August, in drills from 6 to 9 in. apart, the plants being thinned out to 5 or 6 in. in the row. The roots become fit for use during the autumn. For winter use they should be taken up before severe frost sets in, and stored in dry sand. Radishes, like other fleshy roots, are attacked by insects, the most dangerous being the larvae of several species of fly, especially the radish fly (Anthomyia radicam). The most effectual means of destroying these is by watering the plants with a dilute solution of carbolic acid, or much diluted gas-water; or gas-lime may be sprinkled along the rows.

Forcing.—To obtain early radishes a sowing in the British Isles should be made about the beginning of November, and continued until early in February. Generally the radishes will be ready early in March, and may be fit for use about six weeks after sowing. The seed should be sown in light rich soil, 9 or 9 in. thick, on a moderate hothed, or in a pit with a temperature of from 55° to 65°. Gentle waterings must be given, and air admitted at every favourable opportunity, but the rushes must be protected at night and in frosty weather with straw mats or other materials. Some of these crops are often grown with forced potatoes. The best forcing crops are Wood's early frame, the, early dwarf-top scarlet turnip, and early dwarf-top white turnip.

Those best suited for general cultivation are the following:—

Spindle-rooted.—Long scarlet, including the sub-varieties scarlet showing, early frame scarlet, and Wood's early frame; long scarlet short-top, best for general crop.

Turnip-rooted.—Early rose globe-shaped, the earliest of all; early dwarf-top scarlet turnip, and early dwarf-top white turnip; early white short-leaved, early white short-leaved, both very early sorts; French breakfast, olive-shaped; red turnip and white turnip, for summer crops.

WINTER sorts.—Black Spanish, white Chinese, Californian mammouth.

RADIUS (from Lat. radius, ray), a metallurgical chemical element derived from pitchblende, a uranium mineral, by P. and Mme. Curie and G. Bémont in 1896. It was so named on account of the intensity of the radioactive emanations which it yielded. Its discovery was a sequel to H. Becquerel's observation in 1896 that certain uranium preparations emitted a radiation resembling the X rays observed by Röntgen in 1895. Like the X rays, the Becquerel rays are invisible; they both traverse thin sheets of glass or metal, and cannot be refracted; moreover, they both ionize gases, i.e. they discharge a charged electroscope, the latter, however, much more feebly than the former. Characteristic, also, is their action on a photographic plate, and the phosphorescence which they occasion when they impinge on zinc sulphide and other salts. Notwithstanding these resemblances, these two sets of rays are not identical. Mme. Curie, regarding radioactivity—i.e. the emission of rays like those just mentioned—as a property of some undiscovered substance, submitted pitchblende to a most careful analysis. After removing the uranium, it was found that the bismuth separated with a very active substance—polonium; this element was afterwards isolated by Marcwald, and proved to be identical with his radotellurium; that the barium could be
separated with another active substance—radium; whilst a third fraction, composed mainly of the rare earths (thorium, &c.), yielded to Delbrueck another radioactive element—actinium, which proved to be identical with the emanation of Giesel. Another radioactive substance—ionium—was isolated from carnotite, a uranium mineral, by B. B. Boltwood in 1905. Radioactive properties have also been ascribed to other elements, e.g. thorium and lead. There is more radium than any other radioactive element, but its excessive rarity may be gauged by the facts that Mme. Curie obtained only a fraction of a gramme of the chloride and Giesel 2 to 3 gramme of the bromide from a ton of uranium residues.

There is a mass of evidence to show that radium is to be regarded as an element, and in general its properties resemble those of the metals of the alkaline earths, more particularly barium. To the bunsen flame a radium salt imparts an intense carmine-red colour (barium gives a green). The spectrum, also, is very characteristic. The atomic weight, 220.4, places the element in a vacant position in group II of the periodic classification, along with the alkaline earth metals.

Generally speaking, the radiation is not simple. Radium itself emits three types of rays: (1) the α rays, which are regarded as positively charged helium atoms; these rays are stopped by a single sheet of paper; (2) the β rays, which are identified with the cathode rays, i.e. as a single electron charged negatively; these rays can penetrate sheets of aluminium, glass, &c., several millimetres thick; and (3) the γ rays—which are non-electrified radiations characterized by a high penetrating power, 1% surviving after traversing 7 cm. of lead or 150 cm. of water. In addition, radium evolves an "emanation" which is an extraordinarily inert gas, recalling the "inactive" gases of the atmosphere. We thus see that radium is continually losing matter and energy as electricity; it is also losing energy as heat, for, as was observed by Curie and Labarde, the temperature of a radium salt is always a degree or two above that of the atmosphere, and they estimated that a gramme of pure radium would emit about 100 gramme-calories per hour.

The Becquerel rays have a marked chemical action on certain substances. The Curies showed that oxygen was convertible into ozone, and Sudborough that yellow phosphorus gave the red modification when submitted to their influence. More interesting are the observations of D. Berthelot, F. Bordas, C. Dauter, and others, that the rays induce important changes in the colours of many minerals. (See Radioactivity.)

The action of radium on human tissues was unknown until 1901, when, Professor Becquerel of Paris having incautiously carried a tube in his waistcoat pocket, there appeared on the skin within fourteen days a severe inflammation which was known as the famous "Becquerel burn." Since that time active investigation into the action of radium on diseased tissues has been carried on, resulting in the establishment in Paris in 1906 of the "Laboratoire biologique du Radium." Similar centers for study have been inaugurated in other countries, notably one in London in 1909. The diseases to which the application has been hitherto confined are papillomata, lupus vulgaris, epithelial tumours, syphilitic ulcers, pigmented naevi, angioma, and pruritus and chronic itching of the skin; but the use of radium in therapeutics is still experimental. The different varieties of rays used are controlled by the inter- vention of screens or filtering substances, such as silver, lead or aluminium. Radium is analgesic and bactericidal in its action. See Radiumtherapie, by Wickham and Degrais (1909); Die therapeutische Wirkung der Radiumstrahlen, by O. Lasar, in Report of Radiology Congress, Brussels, 1906; E. Dorn, E. Baumann and S. Seitz in Physiologische Zeitung (1905); Abbé in Medical Record (October 1907).

RADIUS, properly a straight rod, bar or staff, the original meaning of the Latin word, to which also many of the various meanings seen in English were attached; it was thus applied to the spokes of a wheel, to the semi-diameter of a circle or sphere, and to a ray or beam of light, "ray" itself coming through the Fr. raie from radius. From this last sense comes "radiant," "radiation," and allied words. In mathematics, a radius is a straight line drawn from the centre to the circumference of a circle or to the surface of a sphere; in anatomy the name is applied to the outer one of the two bones of the fore-arm in man or to the corresponding bone in the fore-leg of animals. It is also used in various other anatomical senses in botany, ichthyology, entomology, &c. A further application of the term is to an area the extent of which is marked by the length of the radius from the point which is taken as the centre; thus, in London, for the purpose of reckoning the fare of hackney-carriages, the radius is taken as extending four miles in any direction from Charing Cross.

RADNOR, EARSLS OF. The 1st earl of Radnor was John Robartes (1606-1683); who succeeded his father, Richard Robartes, as 2nd baron Robartes of Truro in May 1634, the barony having been purchased under compulsion for £10,000 in 1625. The family had amassed great wealth by trading in tin and wool. Educated at Exeter College, Oxford, John Robartes fought on the side of the Parliament during the Civil War, being present at the battle of Edgehill and at the first battle of Newbury, and was a member of the committee of both kingdoms. He is said to have persuaded the earl of Essex to make his ill-fated march into Cornwall in 1644; he escaped with the earl from Lostwithiel and was afterwards governor of Plymouth. Between the execution of Charles I. and the restoration of Charles II. he took practically no part in public life, but after 1660 he became a prominent public man, owing his prominence partly to his influence among the Presbyterians, and ranged himself among Clarendon's enemies. He was lord deputy of Ireland in 1666-1661 and was lord lieutenant in 1669-1670; from 1661 to 1673 he was lord privy seal, and from 1679 to 1684 lord president of the council. In 1679 he was created viscount Bodmin and earl of Radnor, and he died at Chelsea on the 17th of July 1685. His eldest son, Robert, viscount Bodmin, who was British envoy to Denmark, having predeceased his father, the latter was succeeded as 2nd earl by his grandson, Charles Boscwile Robartes (1668-1728), who was a member of parliament under Charles II. and James II., and was lord lieutenant of Cornwall from 1696 to 1705 and again from 1714 to 1723. Henry, the 3rd earl (c. 1690-1741), was also a grandson of the 1st earl, and John, the 4th earl (c. 1686-1755), was another grandson. When John, whose father was Francis Robartes (c. 1650-1718), a member of parliament for over thirty years and a musician of some repute, died unmarried in July 1757, his titles became extinct.

Langly, near Bodmin, and the other estates of the Robartes family passed to the earl's nephews, Thomas and George Hunt. Thomas Hunt's grandson and heir, Thomas James Agar-Robartes (1808-1883), a grandson of an Irish peer, James Agar, 1st viscount Clifden (1734-1789), was created baron Robartes of Langly and of Truro in 1866, after having represented East Cornwall in seven parliaments. His son and successor, Charles Agar-Robartes, 2nd baron (b. 1844), succeeded his kinsman as 6th viscount Clifden in 1890.

In 1795 William Bouverie, 2nd viscount Folkestone (1725-1776), son of Sir Jacob Bouverie, bart. (d. 1761), of Longford, Wiltshire, who was created viscount Folkestone in 1747, was made earl of Radnor. Descended from a Huguenot family, William Bouverie was a member of parliament from 1747 until he succeeded to the peerage in February 1761. He died on the 28th of January 1776. His son and successor, Jacob, the 2nd earl (1750-1828), who took the name of Pleydell-Bouverie in accordance with the will of his maternal grandfather, Sir Mark Stuart Pleydell, bart. (d. 1768), was the father of William Pleydell-Bouverie, the 3rd earl (1779-1866), a politician of some note. In 1900 his great-grandson, Jacob Pleydell-Bouverie (b. 1868), became 6th earl of Radnor.

RADNORSHIRE (St Faesyfed), an inland county of Wales, bounded N. by Montgomery, N.E. by Shropshire, E. by Hereford, S. and W. by Brecknock and N.W. by Cardigan. This county, which is lozenge-shaped, contains 471 sq. m., and is
consequently the smallest in area of the six South Welsh counties. Nearly the whole surface of Radnorshire is hilly or undulating, whilst the centre is occupied by the mountainous tract known as Radnor Forest, of which the highest point attains an elevation of 2163 ft. Towards the S. and S.E. the hills are less lofty, and the valleys broaden out into considerable plains abounding in rivulets. The hills for the most part present smooth, rounded outlines, and are covered with heather, bracken and short grass, though tracts of boggy soil in the uplands are not uncommon. There are rich pastures and numerous woods in the valleys of the Wye and Teme. The Wye Valley has long been celebrated for its beauty, while Radnor Forest and the wild district of Cwmmaiddwr present striking views of primeval and unspoiled scenery. Radnorshire is well supplied with water, its principal river being the Wye (Gwy), which, after crossing the N.W. corner of the county, forms its boundary from Rhayader toward to the English border. Salmon, trout and grayling are plentiful, and the Wye is consequently much frequented by anglers; as are also its tributaries—the Elan (which has been utilized for the great Birmingham reservoirs) the Ithon, the Edw or Edwy, the Lug, the Arrow and the Somergil. The Teme, which divides Radnor from Shropshire on the N.E., is a tributary of the Severn. All these streams are clear and rapid, and abound in fish. In the numerous rocky ravines of the mountainous districts are found many waterfalls, of which the most celebrated is "Water-break-its-Neck," to the W. of New Radnor. Omitting the artificially constructed reservoirs in the valleys of the Elan and Claerwen, the lakes of Radnorshire are represented only by a few pools of which Llynbychlyn near Paincastle is the largest.

Geology.—Ordovician rocks occupy most of the western side of the county, the older Silurian and Carboniferous strata in the south-east. The Silurian formations are the Llandover, Wenlock and Ludlow beds in the order here given. East of New Radnor an inlier of Wenlock rocks is surrounded by Ludlow beds; while at Old Radnor a ridge of very ancient rocks appears in relief. In the south-east of the county Old Red Sandstone rests upon the Silurian. Between Llandrindod, where there are saline, sulphurous and chalybeate wells, and Builth, is a district of Ordovician strata with masses of andesitic and diablastic igneous residue. In the vicinity of Rhayader the strata have been classed as the Rhayader pale rocks (Taranan), the Caban group (Upper Llandover), the Gwastaden group (Lower Llandover); these rest upon shales of Bala age.

Climate and Industries.—The climate of Radnorshire is bracing. If some parts are dry and the rainfall is not so heavy as in the neighboring counties of Montgomery and Brecknock, but thick drizzling mist is of constant occurrence. The winters are often very severe, and deep snowfalls are not uncommon. Good hay and tolu, often a year old, are raised in the valleys and on the upland districts of the county. There has been a long history of sheep farming in the county. The quality of the wool of Radnorshire has long been celebrated, and also the delicacy of the Welsh mutton of the small sheep that are bred in this county. The most important sheep fairs are held at Rhayader, which also contains some woolen factories. There are many small mining industries, and the lead and zinc of the Greenford mines are of some importance. On the other hand, the coal is of very inferior quality. The county has long been noted as an agricultural county, and its produce is of great value. The valley of the Wye is rich in medicinal springs, and the saline, sulphur and chalybeate waters of Llandrindod have long been famous and profitable, and are growing in importance.

Communications.—The Central Wales branch of the London & North-Western railway enters the county at Knighton, traverses it by way of Llandrindod and passes into Brecknock at Builth Road, by the same route. The South Wales railway, after passing through the N.W. corner of the county to Rhayader, follows the course of the Wye, by way of Builth and Hay. Two small branch lines connect New Radnor and Presteigne with the system of the Great Western.

Population and Administration.—The area of Radnorshire is 301,164 acres, and the population in 1891 was 21,791, while in 1901 it had risen to 23,362; an increase chiefly due to the immigration of outside labourers to the Elan Valley waterworks.

The county is divided into the districts of Rhayader, Builth Wells, Brecon, Knighton, Llandrindod and Presteigne, which are each under a commissioner, and the parliamentary division of Radnor, including the town of Knighton. The county is represented in Parliament by a member for Radnor, returned by the boroughs of Knighton, Cefnllys (2167), Presteigne (1617-1670), Llandrindod, Brecon, Builth, and Rhayader (1215). All, except Rhayader, being urban districts. Radnorshire is included in the South Wales circuit, and assizes are held at Presteigne, which ranks as the county town. There is no existing parliamentary borough, and the whole county returns one member to parliament. Ecclesiastically, Radnorshire is divided into 46 parishes, of which 38 lie in the diocese of St Davids, and 8 in that of Hereford.

History.—The wild district of Maesyfed (a name of which the derivation is much disputed), corresponding substantially with the modern Radnorshire, originally formed part of the territory of the Silures, who were vanquished by the Romans. Christianity seems to have been introduced into this barren region during the 5th and 6th centuries by itinerant Celtic missionaries, notably by St David, St Padarn and St Cynilo. Towards the close of the 9th century Maesyfed was absorbed into the middle kingdom of Powys, and in the 10th century it was included in the realm of Elystan Glodrui, prince of Tewys, or Feryllwg, who ruled over all land lying between the Wye and Severn. In the reign of William the Conqueror, the Normans began to penetrate into Maesyfed, where, according to Domesday Book, the king already laid claim to Radenoure, or Radnor (a name of doubtful meaning), in the lordship of Melenith (Moeqlainvaid), which was subsequently bestowed on the Mortimer family, when castles were erected at Old Radnor (Penygraig), New Radnor and Cefnllys. Later, the Norman invaders forced their way up the Wye Valley, the de Breos family, lords of Elvel (Elfæl), building fortresses at Paincastle and at Colwyn or Maud's Castle. In 1188 Archbishop Baldwin, accompanied by Ranulf de Glanville and Giraldis Cambrensis, entered Wales for the purpose of preaching the Third Crusade, and was met in full state at New Radnor by the Lord Rhys, prince of South Wales. The Wye Valley long formed one of the debatable districts between Welsh and Normans, and in 1268 Llewelyn ap Griffith, prince of Wales, was at Aberedw shortly before his death in a skirmish with the Normans. After the battle of Evesham, the whole of the district of Maesyfed remained under the immediate jurisdiction of the Lords-Marchers, represented by the great families of Mortimer and Tudor. During the summer of 1402 Owen Glendower entered the Marches and raided the lands of the young Edward Mortimer, earl of March, whilst the royal troops were severely defeated at the battle of Bryn Gisly near Pillole. By the Act of Union (1536) Maesyfed was erected out of the suppressed lordships into an English shire on the usual model. For administrative purposes it was now divided into six hundreds, and assizes were ordained to be held in alternate years at Presteigne and New Radnor. The newly created county was likewise privileged to return two members to parliament; one for the county, and one for the united boroughs of New Radnor, Rhayader, Knighton, Cefnllys and Knocklas (Cwchlas). The parliamentary district of the Radnor boroughs was, however, disfranchised and merged in the county representation under the Act of 1885. The shire of Radnor with its immense tracts of sheep-walk, its absence of large towns and its sparse rural population has always been reckoned the poorest and least important of the Welsh counties, nor since its creation under Henry VIII. has it ever played a prominent part in the national life of Wales. During the Commonwealth the local clergy were made to suffer severely under the drastic administration of Vavasor Powell (1617-1670), himself a Radnorshire man as a native of Knocklas. Of recent years the rise of Llandrindod as a fashionable watering-place and the construction of the Birmingham reservoirs in the Elan Valley have tended to increase the material prosperity of the county.

Among the leading families of Radnorshire, may be mentioned Lewis of Harpton Court; Baskerville of Clyro; Thomas (formerly Jones) of Pen-cerrig; Lewis-Lloyed of Nan-gwyllt; Gwynne of Llanddewd, and Prickard of Dderw. The older districts of the county abound in numerous memorials of early British times, of which the entrenchment called Crug-y-buddair in the parish of Beguildy is specially worthy of note. Of Roman remains, the most important are those of the fortified camp at Cwm near Llandrindod, which is believed to be identical.
with the military station of Magos or Magna. The course of Offa’s Dyke (Clawdd Ofa) is perceptible at various points in the hilly regions west of Knighton and Presteigne. Very slight traces exist of the many castles erected at various times after the Norman invasion. The parish churches of Radnorshire are for the most part small and of rude construction, and many of them have been modernized or rebuilt. The churches at Old Radnor, Presteigne and Llanbister, however, are interesting edifices, and a few possess fine oaken screens, as at Llananno and Llandegley. There was only one monastic house of consequence, the Cistercian abbey of St Mary, founded by Cadwallon ap Madoc in 1143 in “the long valley” of the Clywedog, six miles east of Rhayader, and from its site commonly called Abbey Cwm Hir. Its existing ruins are insignificant, but the proportions of the church, which was 238 ft. long, are still traceable. The modern mansion adjoining, known as Abbey Cwm Hir, was for some generations the residence of the Fowler family, once reputed the wealthiest in the county.

Customs, &c.—Although in most instances the old Celtic place-names survive throughout the western portion of the county, it is only in the wild remote districts of Cwmduddwr and St Harmon’s that the Welsh tongue predominates, and in this region some of the old Welsh superstitions linger amongst the peasants and shepherds of the hills. In the eastern part of the county English is spoken universally, and the manners and customs of the inhabitants differ little from those prevailing in the neighbouring county of Hereford. On the western side of Radnor Forest the modern spirit of progress has destroyed most of the old local customs. Until the beginning of the 19th century the ancient Welsh service of the *pilgynon* on Christmas morning was observed in Rhayader church; and the same town was formerly remarkable for an interesting ceremony, evidently of great antiquity, whereby after a funeral each attendant mourner was wont to throw a stone upon a certain spot near the church with the words “Carn ar dy ben” (a stone on thy head). The laying of malicious sprites by means of lighted tapers was formerly practised in the churches of the Wye Valley; and a curious service, commemorative of the dead and known as “the Month’s End,” is still observed in certain parish churches, a month after the actual funeral has taken place. The practice of farmers and their wives or daughters riding to the local markets on ponies, the older women sometimes knitting as they proceed, still continues, and is specially characteristic of agricultural life in Radnorshire.

See A General History of the County of Radnor (compiled from the MS. of the late Rev. Jonathan Williams and other sources) (Brecknock, 1905).

**RADOM,** a government of Russian Poland, occupying a triangular space between the Vistula and Pilica, and bounded N. by the governments of Warsaw and Siedlce, E. by Lublin, S. by the crownland of Austrian Galicia and the Polish government of Kielce, and W. by that of Piotrków. The area is 4768 sq. m. Its southern part stretches over the well-watered Sandomier heights, a series of short ranges of hills, 800 to 1000 ft. in altitude, intersected by deep valleys, which running west and east and drained by tributaries of the Vistula, are excellently adapted for agriculture. In its central parts, the government is level, the soil fertile, and the surface, which is diversified here and there with wood, is broken up by occasional spurs (800 ft.) of the Lyssa Góra Mountains. The northern districts consist of low, flat tracts with undefined valleys, exposed to frequent floods and covered over large areas with marshes; the basin of the Pilica, notorious for its unhealthiness, is throughout a low marsh plain. Devonian, Carboniferous, Permian and Triassic deposits appear in the south, Cretaceous and Jurassic in the middle, and Tertiary in the north. Extensive tracts are covered with Glacial deposits,—the Scandinavian erratics reaching as far south as Liza; these last in their turn are overlain by widespread post-Glacial lacustrine deposits. The climate is cold and moist, the mean temperature for the year being 47°-5 Fahr., for January -5° 8, and for July 77°. The Vistula skirts the government on the south and east, and is an important means of communication, steamers plying as far up as Sandomir (Spodnierz). The Sandomir district suffers occasionally from disastrous inundations of the river. The tributaries of the Vistula are short and small, those of the Pilica are sluggish streams meandering amidst marshes. The estimated population in 1906 was 932,800. The government is divided into seven districts, the chief towns of which are Radom, Iza, Konskie, Kozienice, Opatów, Opoczno and Sandomir. Out of the total area about 50% is under cultivation and 28% under forests. The principal crops are wheat, rye, barley, oats, buck-wheat, hemp, flax and potatoes, these last chiefly cultivated for distilleries. Grain is exported. Live stock is kept in large numbers. Manufactures have considerably developed of late years, the government being rich in iron ore, while coal and zinc occur, as also marble, gypsum, alabaster, potters’ clay and red sandstone. The iron industry occupies more than 60,000 workmen, and turns out annually some 100,000 tons of pig iron, 25,000 tons of iron, and 150,000 tons of steel. There are several sugarworks, tanneries, flour-mills, machine works, distilleries, breweries and brickworks. Trade is not very extensive, the only channel of commerce being the Vistula. (P. A. K., J. T. BE.)

**RADOVISYLS, formerly MyCHEK,** a town of Russia, in the government of Kiev, 31 m. W. of the city of Kiev, on the Teteriv river. Pop. 18,154. It is a very old town, being mentioned in 1150; from 1746 to 1795 it was the residence of the metropolitan of the United Greek Church. It has tanneries and flour-mills, and exports timber, corn and mushrooms.

**RADOVITZ, JOSEPH MARIA VON** (1797-1853), Prussian general and statesman, was born at Blankenburg in the Harz Mountains, his family being of Hungarian origin. As a young lieutenant in the Westphalian artillery he was wounded and taken prisoner at the battle of Leipzig (1813), subsequently entered the Hanoverian service, and in 1823 that of Prussia. His promotion was rapid, and in 1830 he became chief of the general staff of the artillery. In 1836 he went as Prussian military plenipotentiary to the federal diet at Frankfurt, and in 1842 was appointed envoy to the courts of Carlsruhe, Darmstadt and Nassau. He had early become an intimate friend of the crown prince (afterwards King Frederick William IV.), and the Prussian constitution of February 1847 was an attempt to realize the ideas put forward by him in his *Gespräche aus der Gegenwart über Staat und Kirche,* published under the pseudonym “Waldheim” in 1846. In November 1847 and March 1848 Radovitz was sent by King Frederick William to Vienna to attempt to arrange common action for the reconstruction of the German Confederation. In the Frankfurt parliament he was leader of the extreme Right; and after its break-up he was zealous in promoting the Unionist policy of Prussia, which he defended both in the Prussian diet and in the Erfurt parliament. He was practically responsible for the foreign policy of Prussia from May 1848 onwards, and on the 27th of September 1852...
he was appointed minister of foreign affairs. He resigned, however, on the 29th of November, owing to the king's refusal to settle the difficulties with Austria by an appeal to arms. In August 1852 he was appointed director of military education; but the rest of his life was devoted mainly to literary pursuits. He died on the 25th of December 1853. 

Radovitz published, in addition to several political treatises, *Ikonographie der Heiligen, ein Beitrag zur Kunigschätze* (Berlin, 1854) and *Denvis und Motivs des spätern Mittelalters* (ib. 1850). His Gesammelte Schriften were published in 8 vols. at Berlin, 1852–55. See Hassel, *Joseph Maria von Radovitz* (Berlin, 1905, &c.).

**RAE—RAEBURN**

**RAE, JOHN** (1813–1893). Scottish Arctic explorer, was born on the 30th of September 1813, in the Orkney Islands, which he left at an early age to study medicine at Edinburgh University, qualifying as a surgeon in 1833. He made a voyage in a professional capacity in one of the ships of the Hudson's Bay Company, and entering the service of the company was resident surgeon for ten years at their station at Moose Factory, at the head of James Bay. In 1846 he made a boat-voyage to Repulse Bay, and having wintered there, in the following spring surveyed 700 miles of new coast-line connecting the earlier surveys of Ross and Parry. An account of this expedition, *A Narrative of an Expedition to the Shores of the Arctic Sea in 1846 and 1847*, was published by him in 1850. During a visit to London in 1848 he joined the expedition which was then preparing to go out under Sir John Richardson in search of Franklin; and in 1851, at the request of the Government and with a very slender outfit, he travelled some 5000 miles, much of it on foot, to the north-west coast of America, and explored the south side of Wollaston and Victoria Lands. For this achievement he received the Founder's gold medal of the Royal Geographical Society. In 1853 he commanded another boat-expedition which was fitted out by the Hudson's Bay Company, which connected the surveys of Ross with that of Deane and Simpson, and proved King William's Land to be an island. It was on this journey that he obtained the first authentic news regarding the fate of Franklin, thereby winning the reward of £10,000 promised by the admiralty. He subsequently travelled across Iceland, and in Greenland and the northern parts of America, surveying routes for telegraph lines. Dr Rae attributed much to his success in Arctic travel to his adoption of the methods of the Eskimo, a people whom he had studied very closely. He was a keen sportsman, an accurate and scientific observer. He died at his house in London and was buried in the Orkney Islands.

**RAE BARELI**, a town and district of British India, in the Lucknow division of the United Provinces. The town is on the river Sai, 48 m. S.E. of Lucknow, on the Oudh & Rohilkhand railway. Pop. (1901) 15,880. It possesses many architectural features, chief of which is a strong and spacious fort erected in 1403, and constructed of bricks 2 ft. long by 1 ft. thick and 1½ wide. Among other ancient buildings are the magnificent palace and tomb of Nawab Jahan Khan, governor in the time of Shah Jahan, and four fine mosques. The town is an important centre of trade, and muslins and cotton cloth are woven.

The district of Rae Bareli has an area of 1748 sq. m. The general aspect of the district is slightly undulating, and the country is beautifully wooded. The soil is remarkably fertile, and the cultivation of a high class. The principal rivers of the district are the Ganges and the Sai: the former skirts it for 54 miles and is everywhere navigable for boats of 40 tons; the latter traverses it from N.W. to S.E. In the 19th century the average rainfall was 1,033,761, showing a slight decrease during the decade. The principal crops are rice, pulse, wheat, barley, millet and poppy. Rae Bareli town is connected with Lucknow by a branch of the Oudh & Rohilkhand railway, which in 1898 was extended to Benares.

See Rae Bareli District Gazetteer, Allahabad, 1905.

**RAEBURN, SIR HENRY** (1756–1823). Scottish portrait-painter, was born at Stockbridge, a suburb of Edinburgh, on the 4th of March 1756, the son of a manufacturer of the city. He was early left an orphan. Being placed in Heriot's Hospital, he received there the elements of a sound education, and at the age of fifteen was apprenticed to a goldsmith in Edinburgh. Here he had some little opportunity for the practice of the humbler kinds of art, and various pieces of jewelry, mourning rings, and the like, adorned with minute drawings on ivory by his hand, are still extant. Soon he took to the production of carefully finished miniatures; and, meeting with success and patronage, he extended his practice to oil-painting, being all the while quite self-taught. The worthy goldsmith his master watched the progress of his pupil with interest, gave him every encouragement, and introduced him to David Martin, who had been the favourite-assistant of Allan Ramsay junior, and was now the leading portrait-painter in Edinburgh. Raeburn received considerable assistance from Martin, and was especially aided by the loan of portraits to copy. Soon the young painter had gained sufficient skill to render it advisable that he should devote himself exclusively to painting. When he was in his twenty-second year he was asked to paint the portrait of a young lady whom he had previously observed and admired when he was sketching from nature in the fields. She was the daughter of Peter Edgar of Bridgelands and widow of Count Leslie. The lady was speedily fascinated by the handsome and intellectual young artist, and in a month she became his wife, bringing him an ample fortune. This early insurance against the risks of his chosen profession, did not, however, diminish his anxiety to excel. The acquisition of wealth affected neither his enthusiasm nor his industry, but rather spurred him to greater efforts to acquire a thorough knowledge of his craft. After the approved fashion of artists of the time, it was resolved that Raeburn should visit Italy, and he accordingly started with his wife. In London he was kindly received by Sir Joshua Reynolds, who gave him excellent advice as to his study in Rome, especially recommending to his attention the works of Michelangelo. He returned to London, and in 1785, through the medium of the Goldscheider, who was a collector of pictures, which it was as a medium of exchange but not as a seer, Raeburn carried with him to Italy many valuable introductions from the president of the Academy. In Rome he made the acquaintance of Gavin Hamilton, of Batoni, and of Byer. For the advice of the last-named he used to acknowledge himself greatly indebted, particularly for the recommendation that "he should never copy an object from memory, but, from the principal figure to the minutest accessory, have it placed before him." After two years of study in Italy he returned to Edinburgh in 1787, where he began a most successful career as a portrait-painter. In that year he executed an admirable seated portrait of the second Lord President Dundas.

Of his earlier portraiture we have interesting examples in the bust-likeeness of Mrs Johnstone of Baldovie and in the three-quarter-length of Dr James Hutton, works which, if they are somewhat timid and tentative in handling and wanting in the correct brush-work and assured mastery of subsequent productions, are full of delicacy and character. The portraits of John Clerk, Lord Eldin, and of Principal Hill of St Andrews belong to a somewhat later period. Raeburn was fortunate in the time in which he practised portraiture. Sir Walter Scott, Blair, Mackenzie, Woodhouselee, Robertson, Home, Ferguson, and Dugald Stewart were resident in Edinburgh, and they all, along with a host of others less celebrated, honoured the painter's canvases. Of his fully matured manner we could have no finer examples than his own portrait and that of the Rev. Sir Henry Moncrieff Wellwood, the bust of Dr Wardrop of Torbane Hill, the two full-lengths of Adam Rolland of Gask, the remarkable paintings of Lord Newton and Dr Alexander Adam in the National Gallery of Scotland, and that of William Macdonald of St Martin's. It was commonly believed that Raeburn was less successful in his female than in his male portraits, but the exquisite full-length of his wife, the smaller likeness of Mrs R. Scott Moncrieff in the Scottish National Gallery, and that of Mrs Robert Bell, and others, are sufficient to prove that he could portray all the grace and beauty of the gentler sex.
RÆDWALD—RAETIA

Raeburn spent his life in Edinburgh, rarely visiting the metropolis, and then only for brief periods, thus preserving his own sturdy individuality, if he missed the opportunities of engraving himself. He exhibited works of portraiture and of engraving in some of the most important exhibitions of his day; and from contact with a wider public, Scottish art certainly gained much from his disinclination to leave his native land. He became the acknowledged chief of the school which was growing up in Scotland during the earlier years of the 19th century, and to his example and influence at a critical period is undoubtedly due much of the striking vitality by which the work of his followers and immediate successors is distinguished. Evidences of this influence can be perceived even in the present day. His leisure was employed in athletic sports, in his garden, and in architectural and mechanical pursuits, and so varied were the interests that filled his life that his sitters used to say of him, “You would never take him for a painter till he seizes the brush and palette.” Professional honours fell thick upon him. In 1812 he was elected president of the Society of Artists in Edinburgh, in 1814 associate, and in the following year full member. In 1817 he was knighted by George IV. and appointed His Majesty’s lieutenant for Scotland. He died at Edinburgh on the 8th of July 1823.

In his own day the portraits of Raeburn were excellently and voluminously engraved, especially by the last members of the great school of English mezzotint. In 1876 a collection of over 300 of his works was brought together in the Royal Scottish Academy galleries; in the following year a series of twelve of his finest portraits was included in the winter exhibition of the Royal Academy, London; and a volume of photographs from his paintings was edited by Dr John Brown.

Raeburn possessed all the necessary requirements of a popular and successful portrait-painter. He had the power of producing a telling and forcible likeness; his productions are distinguished by breadth of effect, by admirable force of handling, by execution of the sweetest and most resolute sort. Wilkie has recorded that, while travelling in Spain and studying the works of Velasquez, the brush-work of that master reminded him constantly of the “square touch” of Raeburn. But the portraits of Velasquez show a certain coldness of touch, and it is in the former quality that Raeburn is often wanting, possibly because his inclinations led him to study effects of diffused light in preference to those which were strong in contrasts of light and shade. The colour of his portraits is sometimes crude and out of relation, inclining to the use of positive and definite local pigments, and too little perceptive of the changeable subtleties and modifications of atmospheric effect. His draperies frequently consist of little more than two colours—the local hue of the fabric and the black which, more or less graduated, expresses its shadows and modelling. In his flesh, too, he wants—in all but his very best productions—the delicate refinements of colouring which distinguish the works of the great English portrait-painters. His faces, with all their excellent truth of form and splendid vigour of handling, are often hard and bricky in hue. Yet, after all allowances have been made for what deficiencies there may be in his work, his right to a place among the greater British masters cannot be contested. The masculine power, the vitality and the strength of character, the portions which are so apparent in his paintings entitle him to the serious attention of the student and critic, and there is much to be learned from study of his methods. His sincerity and freedom from artificial graces of style can be specially recognized, and his frank directness is always attractive.

See Life of Sir Henry Raeburn, R.A., by his great-grandson William Raeburn Andrew, M.A. Oxon. (2nd ed., 1894), which contains some of the latest information, together with a complete catalogue of the exhibition of 1876. There may also be consulted Works of Sir Henry Raeburn, R.A., with tributes by Dr John Brown and others, published by Andrew Elliot, Edinburgh; Tribute to the Memory of Raeburn by Dr Andrew Duncan, the Catalogues of the loan exhibitions in Edinburgh of 1884 and 1901; and the Essay by W. E. Henley—Sir Henry Raeburn by William Ernest Henley (1890) with a finely produced series of plates, printed by T. & A. Constable for the new defunct Royal Association for Promotion of the Fine Arts in Scotland. But the leading work on the subject, and the most splendidly illustrated, is Sir Henry Raeburn by Sir Walter Armstrong, with an introduction by R. A. M. Stevenson and a biographical and descriptive catalogue by J. L. Caw (1901).

RÆDWALD (d. c. 620), king of the East Angles, was the son of King Tytic. He became a Christian during a stay in Kent, but on his return to East Anglia he sanctioned the worship both of the Christian and the heathen religions. Very little is known about his reign, which probably began soon after 600. For a time he recognized the overlordship of Æthelberht, king of Kent, but he seems to have shaken off the Kentish yoke. He gained some superiority over the land south of the Humber with the exception of Kent and is counted among the Bretwaldas. Ræwald protected the fugitive Edwin, afterwards king of Northumbria, and in his interests he fought a sanguinary battle with the reigning Northumbrian king, Æthelthryth, near Retford in Nottinghamshire, where Æthelthryth was defeated and killed in April 617. He was followed as king of the East Angles by his son Raedwald. Raedwald was employed in many expeditions, but the most important was in 1894, when he was sent, together with his son, to the continent on a fishing expedition (so that, according to the story reported by Justin (xxix. 5) and Pliny (Nat. Hist. iii. 24, 133) in the year 617, it is possible that the ships of that people had settled in the plains of the Po and were driven into the mountains by the invading Gauls, when they assumed the name of Raetians from their leader Raetus; a more probable derivation, however, is from Celtic rait, “mountain land.” Even if their Etruscan origin be accepted, at the time when the land became known to the Romans, Celtic tribes were already in possession of it and had amalgamated so completely with the original inhabitants that, generally speaking, the Raetians of later times may be regarded as a Celtic people, although non-Celtic tribes (Lepontii, Euganei) were settled among them. The Raetians are first mentioned (but only incidentally) by Polybius (xxiv. 10, 18), and little is heard of them till after the end of the Republic. There is little doubt, however, that they retained their independence until their subjugation in 15 B.C. by Tiberius and Drusus (cf. Horace, Odes, iv. 4 and 14). At first Raetia formed a distinct province, but towards the end of the 1st century A.D. Vindelicia was added to it, and Raetia (Graetia) could rank as Augustus, Vindeliciorum (Augsburg) as “a colony of the province of Raetia.” The whole province (including Vindelicia) was at first under a military prefect, then under a procurator; it had no standing army quartered in it, but relied on its own native troops and militia for protection. In the reign of Marcus Aurelius it was governed by the commander of the Legio iii. Italica. Under Diocletian it formed part of the diocese of the vicarius Italici, and was subdivided into Raetia prima and secunda (each under a praeses), the former corresponding to the old Raetia, the latter to Vindelicia. The boundary between them is not clearly defined, but may be
stated generally as a line drawn eastwards from the lacus Brigantinus (Lake of Constance) to the river Oenus (Inn). During the last years of the Western Empire, the land was in a desolate condition, but its occupation by the Ostrogoths in the time of Theodoric, who placed it under a dux, to some extent revived its prosperity. The chief towns of Raetia (excluding Vindelicia) were Tridentum (Trent) and Curia (Coire or Chur). It was traversed by two great lines of Roman roads—one leading from Verona and Tridentum across the Brenner (in which the name of the Brenni has survived) to Oenipons (Innsbruck) and thence to Augusta Vindelicorum, the other from Brigantium (Bregenz) on Lake Constance, by Coire and Chiavenna to Como and Milan.

**RAFF, JOSEPH JOACHIM** (1822–1882), German composer and orchestral conductor, was born near Zürich, Switzerland, on the 27th of May 1822, and educated chiefly at Schwyz. Here, under the care of the Jesuit fathers, he soon became an excellent classical and mathematical scholar, but received scarcely any instruction in his favourite art of music, in which, nevertheless, he made extraordinary progress through sheer force of natural genius, developed by persevering study which no external obstacles could induce him to discontinue. So successful were his unaided efforts that, when in 1843 he sent some MSS. to Mendelssohn, that warm encourager of youthful talent, it felt justified in at once recommending him to Breitkopf & Härtel, the Leipzig publishers, who brought out a large selection of his early works. Soon after this he became acquainted with Liszt, who gave him much generous encouragement. He first became personally acquainted with Mendelssohn at Cologne in 1846, and gave up all his other engagements for the purpose of following him to Leipzig, but his intention was frustrated by the great composer's death in 1847. After this disappointment he remained for some time at Cologne, where his attention was alternately devoted to composition and to the preparation of critiques for the periodical *Cäcilien*. Thus far he was a self-taught artist; but he felt the need of systematic instruction so deeply that, retiring for a time from public life, he entered at Stuttgart upon a long course of severe and uninterrupted study, and with so much success that in 1850 he appeared before Prince Friedrich Wilhelms of Prussia and the chancellor of the city, as an unusually highly cultivated musician. Raff now settled for a time in Weimar in order to be near Liszt. Hans von Bülow had already brought him into notice by playing his *Concertstück* for piano-forte and orchestra in public, and the favour with which this fine work was everywhere received encouraged him to attempt a greater one. During his stay in Stuttgart he had begun the composition of an opera entitled *König Alfred*, and had good hope of securing its performance at Dresden; but the political troubles with which Germany was then overwhelmed rendered its production in the Saxon capital impossible. At Weimar he was more fortunate. In due time *König Alfred* was produced there under Liszt's able direction at the court theatre with complete success; and later, in 1870, he wrote his second opera, *Dame Kolda*, for performance at the same theatre. A third opera, *Senta*, remained unstaged.

Raff lived at Weimar until 1856, when he obtained a large *clientèle* at Wiesbaden as a teacher of the pianoforte. In 1859 he married Doris Genast, an actress of high repute, and thenceforward devoted himself with renewed energy to the work of composition, displaying an inexhaustible fertility of invention tempered by great technical skill. He resided chiefly at Wiesbaden till 1877, when he was appointed director of the Hoch-Conservatorium at Frankfurt, an office which he retained until his death on the 25th of June 1882.

More than 200 of Raff's compositions have been published, including ten symphonies—undoubtedly his finest works—quartets, concertos, sonatas, songs, and examples of nearly every known variety of style; yet he never repeats himself. Notwithstanding his strong love for the romantic school, he is never guilty of extravagance, and, if in his minor works he is sometimes a little commonplace, he never descends to vulgarity. His symphonies *Lenore* and *Im Wald* are wonderful examples of musical painting.

**RAFFAELLO DEL GARBO** (1466, or perhaps 1476–1524), Florentine painter. His real name was Raffaello Capponi; Del Garbo was a nickname, bestowed upon him seemingly from the graceful nicety (garbo) of his earlier works. He has also been called Raffaello de Florentia, and Raffaello de Carolis. He was a pupil of Filippino Lippi, with whom he remained till 1490, if not later. He showed great facility in design, and excited hopes which the completed body of his works fell short of. He married and had a large family; embarrassments and a haphazard manner of work ensued; and finally he lapsed into a very dejected and pensive condition. Three of his best tempera pictures are in the Berlin Gallery; one of the Madonna standing with her Infant between two musician-angels, is particularly attractive. We may also name the oil-painting of the "Resurrection" done for the church of Monte Oliveto, Florence, now in the academy of the same city, ordinarily reputed to be Raffaellino's masterpiece; the ceiling of the Carafa Chapel in the church of the Minerva, Rome; and a "Coronation of the Virgin" in the Louvre, which is a production of much merit, though with somewhat over-studied grace. Angelo Allori was his pupil.

**RAFFET, DENIS AUGUSTE MARIE** (1804–1866), French literary and lithographer, was born in Paris in 1804. At an early age he was apprenticed to a wood-turner, but took up the study of art at evening classes. He became acquainted with Cabanel, who made him apply his skill to the decoration of china, and with Rudor, from whom he received instruction in lithography, in the practice of which he was to rise to fame. He then entered the École des Beaux-Arts, but returned definitely to lithography in 1835, when he produced on stone his famous designs of "Lutzen," "Waterloo," "Le bain," "La revue" and "Les adieux de la garnison," by which his reputation became immediately established. Raffet's chief works were his lithographs of the Napoleonic campaigns, from Egypt to Waterloo, vigorous designs that are inspired by ardent patriotic enthusiasm. As an illustrator his activity was prodigious, the list of works illustrated by his crayon amounting to about forty-five, among which are Granger's poems, the *History of the Revolution* by Thiels, the *History of Napoleon* by Delavignette, the great *Waller Scott* by Defauconpret, the French Plutarch and Frédéric Bérat's *Songs*. He went to Rome in 1840, was present at the siege of Rome, which he made the subject of some lithographs, and followed the Italian campaign of 1859, of which he left a record in his *Episodes de la campagne d'Italie de 1859*. His portraits in pencil and water-colour are full of character. He died at Genoa in 1860. In 1863 a monument by Frémiet was unveiled in the Jardin de l'Infante at the Louvre, Paris.

See Rafel, by F. Lhomme (Paris, 1892).

**RAFFLE, a special kind of lottery, in which a particular article is put up as the prize, the winner being drawn for by lot out of the number of those who have paid a fixed sum for admission to the drawing; the total amount realized by the sale of the tickets is supposed to approximate to the value of the object raffled for. The word appears in English as early as Chaucer (The *Parson's Tale*) where it is used in its original French form, *rafflez* or *raffler* for the purpose of three dice all alike, or, next, the highest pair. The Fr. *rafle*, Med. Lat. *raffa*, was also used in the sense of a "sweeping-off" of the stakes in a game; it has been connected with Ger. *raffen*, to carry off.

**RAFFLES, SIR THOMAS STAMFORD** (1781–1826), English administrator, founder of Singapore, was born on the 5th of July 1781, on board a merchantman commanded by his father. Benjamin Raffles, when of Port Morant, Jamaica. He received
his early education at a school at Hammersmith, but when only fourteen he obtained temporary work in the secretary's office of the East India Company. In 1800 he was appointed junior clerk on the establishment. In 1805 the East India Company decided to make Penang a regular presidency, and sent out a governor with a large staff, including Stamford Raffles, who was appointed assistant-secretary. On the eve of his departure he married Mrs Fancourt (Olivia Mariamme Devenish), widow of a surgeon on the Madras Establishment; she proved herself a helpful wife and counsellor to her husband in his rapid rise to fortune during the following nine years, dying prematurely in Java in November 1814. On his way out to Penang, Raffles began the study of the Malay language, and had mastered its grammar before his arrival. He continued his studies, finding a congenial fellow-worker and kindred spirit in John Leyden, who was invalided to Penang. In August 1806 Raffles was appointed acting secretary during the illness of that official, and in 1807 he received the full appointment. In the meantime he had acted as Malay interpreter, which entailed heavy and unappreciated work in addition to his regular duties. In 1808 his health gave way, and he was ordered for a change to Malacca. This proved a turning-point in his career. The East India Company had decided to abandon Malacca, and orders had been issued to dismantle it. Raffles perfected his study of Malay during his stay at this place, and learning from the Malays, with whom he mixed freely, that the abandonment of so important a position would be a grave fault, he drew up a report explaining the great importance of Malacca, and urging in the strongest manner its retention. This report was sent by the Penang authorities not only to London, but to the governor-general, the earl of Minto. The latter was so impressed by the report that he at once gave orders for suspending the evacuation of Malacca, and in 1809 the company decided to reverse its own decision. When the whole question was calmly considered in the light of subsequent events, many years later, Lord Castlereagh, in his History of Java, stated, "Raffles still preserved the memory of Malacca from the British Crown." A direct correspondence with Lord Minto was established by the mediation of Leyden, who wrote to Raffles that the governor-general would be gratified in receiving communications direct from him. In June 1810, Raffles, of his own accord, proceeded to Calcutta, where Lord Minto gave him the kindest reception. Raffles remained four months in Calcutta, and gained the complete confidence of the governor-general. He brought Lord Minto round to his opinion that the conquest of the island of Java, then in the hands of the French, was an imperative necessity. To prepare the way for the expedition, Raffles was sent to Malacca as "agent to the Governor-General with the Malay States." He did his work well and thoroughly—even to the extent of discovering that the short and direct route to Batavia by the Caramata passage would be safe for the fleet. In August 1811 the expedition, accompanied by Lord Minto, and with Sir Samuel Auchmuty (1763–1849) in command of the fleet, started for Java (the half English and half Indian), occupied Batavia without fighting. On the 25th of the same month a battle was fought at Cornelis, a few miles south of Batavia, and resulted in a complete English victory. On the 18th of September the French commander, General Janssens, formally capitulated at Samarang, and the conquest of the island was completed. Lord Minto's first act was to appoint Raffles lieutenant-governor of Java. From September 1811 until his departure for England in March 1816, Raffles ruled this large island with conspicuous success and the most gratifying results. To give only one fact in support of this statement, he increased the revenue eightfold at the same time that he abolished transit dues, reduced port dues to one-third and removed the fettors imposed on trade and intercourse with the Javanese by Dutch officialdom. In his own words, his administration aimed at being "not only without fear, but without reproach." He had a still greater ambition, which was, in his own words, "to make Java the centre of an Eastern insular Empire," and to establish the closest relations of friendship and alliance with the Japanese, whom he described as "a highly polished people, considerably advanced in science, highly inquisitive and full of penetration." It is interesting to note that when another great Englishman, Rajah Brooke, began his career in Sarawak in 1838, he announced: "I go to carry Sir Stamford Raffles's views in Java over the whole Archipelago."

The policy of Raffles was based on the assumption that Java would be retained, but for reasons of European policy it was decided that it must be restored to Holland. After his return to England in 1816 he endeavoured to obtain a reconsideration of the question, but the decision taken was embodied in a treaty and beyond all possibility of modification. During his stay in England Raffles was knighted by the prince regent, published his History of Java (1817) and discussed with Sir Joseph Banks a project for the foundation in London of a zoological museum and garden on the model of the Jardin des Plantes at Paris. He also married his second wife, Sophia, daughter of T. W. Hull of Co. Down; he had many children by both marriages, but the only one to live beyond childhood was a daughter, who died fifteen years after her father's death, and before she was twenty. He left, therefore, no direct descendants.

In November 1817 Sir Stamford quitted England on his return to the East, where the lieutenant-governorship of Fort Marlborough (Sumatra) had been kept in reserve for him. His administration of Sumatra, which lasted from March 1818 till December 1823, was characterized by the same breadth of view, consistency of purpose and energy in action that had made his government of Java remarkable. He had not, however, done with the Dutch, who, on their recovery of Java, endeavoured to establish a complete control over the Eastern archipelago, and to oust British trade. This design Sir Stamford set himself to baffle, and although he was more frequently censured than praised by his superiors for his efforts, he had already met with no inconsiderable success in minor matters when, by a stroke of genius and a turn of his hand, he stopped for all time the Dutch project of a mare cladum by the acquisition and founding of Singapore on the 29th of January 1819.

In 1824 Sir Stamford returned to England, but unfortunately the differences between him and the East India Company had resulted in an accumulation of disputes which placed a severe strain on his enfeebled constitution. The memorials and statements that he had to compile for his own vindication would fill a large volume, but at last the court passed (14th of April 1826) a formal decision in his favour. It did not omit, however, to censure him for "his precipitate and unauthorized emancipation of the Company's slaves," or after his death to make his widow pay £10,000 for various items, which included the expense of his mission to found Singapore! Harassed as he was by these personal affairs, he still found time to carry out his original scheme with regard to a zoological society in London. He took the largest part in the creation of the existing society, founded in 1826, and when, after his death, it failed to retain the services of his widow, M'Colloch, as its regent, he was unanimously elected its president at the first meeting, and by a remarkable unanimity of opinion on the part of those who helped in the work, he has been recognized as "the Founder of the Zoological Society." He was contemplating entering parliamentary life when his sudden death on his birthday, 1826, ended his brilliant career at the early age of forty-five. Sir Frederick Weld, lieutenant-governor at Singapore, when unveiling the statue of his predecessor at that place in 1887, crystallized the thoughts of his countrymen and anticipated the verdict of history in a single sentence: "In Raffles, England had one of her greatest sons."
views being contained in his chief work, *Antiquitates Americae* (Copenhagen, 1837). See LEIF ERICSSON.

**RAFTER**, a beam in a sloping roof to which is attached the framework for the slating, tiling or other external covering (see Roofs). The O.Eng. *rafter* is cognate with Icel. *raft*, Dan. and Swed. *raste* or *raft*, a beam, which, in the special sense of a floating collection of timbers, gives the English "raft." The ultimate base of these words is the root *raft*-, to cover, seen in Gr. ṭρόφος, roof.

**RAGATZ**, a famous watering-place in the Swiss canton of St Gall, situated on the left bank of the Rhine, and by rail 13½ m. N. of Coire or 61½ m. S.E. of Zürich. It stands at a height of 1696 ft., at the entrance to the magnificent gorge of the Tamina, about 3 m. up which by carriage road are the extraordinarily placed Baths of Pfäfers (2247 ft.). Since 1830 the hot mineral waters of Pfäfers are conducted in pipes to Ragatz, which is in a more pleasant position. Consequently Ragatz has much increased in importance since that date. In 1800 its native population was 1866, mainly German-speaking, while there were 1472 Romanists to 392 Protestants. The annual number of visitors is reckoned at 50,000. In the churchyard is the grave of the philosopher Schelling (d. here in 1854). About 2 m. by road above Ragatz are the 17th-century buildings (now the cantonal lunatic asylum) of the great Benedictine abbey of Pfäfers (720–1838), to which all this region belonged till 1708; while midway between them and Ragatz are the ruins of the 14th-century castle of Wartenstein, now accessible from Ragatz by means of a funicular railway. (W. A. B. C.)

**RAGLAN, FITZROY JAMES HENRY SOMERSET**, 1st Baron Raglan (1788–1855), British field marshal, was the eighth and youngest son of Henry, 5th duke of Beaufort, by Elizabeth, daughter of Admiral the Hon. Edward Boscawen, and was born on the 30th of September 1788. His elder brother, General Lord (Robert) Edward (Henry) Somerset (1776–1842), distinguished himself as a junior officer in the War of the First Coalition, and was sent to Russia in 1807 to join the Army of the Allied Powers commanded by Alexander, and there became the teacher of the Emperor Alexander. Lord Fitzroy Somerset was educated at Westminster school, and entered the army in 1804. In 1807 he was attached to the Hon. Sir Arthur Paget's embassy to Turkey, and the same year he was selected to serve on the staff of Sir Arthur Wellesley in the expedition to Copenhagen. In the following year he accompanied the same general in a like capacity to Portugal, and during the whole of the Peninsular War was at his right hand, first as aide-de-camp and then as military secretary. He was wounded at Busaco, became brevet-major after Fuentes de Oñoro, accompanied the stormers of the 52nd light infantry as a volunteer at Ciudad Rodrigo and specially distinguished himself at the storming of Badajoz, being the first to mount the breach, and afterwards showing great resolution and promptitude in securing one of the gates before the French could organize a fresh defence. During the short period of the Bourbon rule in 1814 and 1815 he was secretary to the English embassy at Paris. On the renewal of the war he again became aide-de-camp and military secretary to the duke of Wellington. About this time he married Emily Harriet, daughter of the 3rd earl of Mornington, and Wellington's niece. At Waterloo he was wounded in the right arm and had to undergo amputation, but he quickly learned to write with his left hand, and on the conclusion of the war resumed his duties as secretary to the embassy at Paris. From 1818 to 1820, and again in 1826–29, he sat in the House of Commons as member for Truro. In 1819 he was appointed secretary to the duke of Wellington as master-general of the ordinance, and from 1827 till the death of the duke in 1852 was military secretary to him as commander-in-chief. He was then appointed master-general of the ordinance, and was created Baron Raglan. In 1854 he was promoted general and appointed to the command of the English troops sent to the Crimea (see Crimea War). He co-operated with a strong French army under Marshal St Arnaud and afterwards, up to May 1855, under Marshal Canrobert. Here the advantage of his training under the duke of Wellington was seen in the soundness of his generalship, and his diplomatic experience stood him in good stead in dealing with the generals and admirals, British, French and Turkish, who were associated with him. But the trying winter campaign in the Crimea also brought into prominence defects perhaps traceable to his long connexion with the formalities and uniform regulations of military offices in peace time. For the hardships and sufferings of the English soldiers in the terrible Crimean winter before Sebastopol, owing to failure in the commissariat, both as regards food and clothing, Lord Raglan and his staff were at the time severely censured by the press and the government; but, while Lord Raglan was possibly to blame in representing matters in a too sanguine light, it afterwards appeared that the chief neglect rested with the home authorities. But this helpfulness was a shining military quality in the midst of the despondency that settled upon the allied generals after their first failures, and at Balaklava and Inkermann he displayed the promptness and resolution of his youth. He was made a field marshal after Inkermann. During the trying winter of 1854–55, the sufferings he was compelled to witness, the censures, in great part unjust, which he had to endure and all the manifold anxieties of the siege seriously undermined his health, and although he found a friend and ardent supporter in his new French colleague, General Pélissier (q.v.), disappointment at the failure of the assault of the 18th of June 1855 finally broke his spirit, and very shortly afterwards, on the 28th of June 1855, he died of dysentery. His body was brought home and interred at Badminton.

His eldest son having been killed at the battle of Ferozeshah (1843), the title descended to his younger son Richard Henry Fitzroy Somerset, 2nd Baron Raglan (1817–1884); and subsequently to the latter's son, George Fitzroy Henry Somerset, 3rd Baron (b. 1857), under-secretary for war 1900–2, lieutenant-governor of the Isle of Man (1902) and a prominent militia officer.

**RAGMAN ROLLS**, the name given to the collection of instruments by which the nobility and gentry of Scotland were compelled to subscribe allegiance to Edward I of England between the conference of Norham in May 1291 and the final award in favour of Baliol in November 1292, and again in 1296. Of the former of these records two copies were preserved in the chapterhouse at Westminster (now in the Record Office, London), and it has been printed by Rymer (*Foedera*, ii. 542). Another copy, preserved originally in the Tower of London, is now also in the Record Office. The latter record, containing the various acts of homage and fealty extorted by Edward from Baliol and others in the course of his progress through Scotland in the summer of 1296 and in August at the parliament of Berwick, was published by Prynne from the copy in the Tower and now in the Record Office. Both records were printed by the Bannatyne Club in 1834. The derivation of the word "ragman" has never been satisfactorily explained, but various guesses as to its meaning, and a list of the Oxford 1854s of its use for legal instruments both in England and Scotland will be found in the preface to the Bannatyne Club's volume, and in Jamieson's *Scottish Dictionary*, s.v. "Ragman." The name "ragman roll" survives in the colloquial "rigmarole," a rambling, incoherent statement.

The name of "Ragman" has been sometimes confined to the record of 1296, of which an account is given in *Calendar of Documents relating to Scotland preserved in the Public Record Office, London* (1884), vol. ii., introd., p. xxiv; and as to the seals see p. lxi and appendix.

**RAG-STONE** (probably equivalent to "ragged" stone), a name given by some architectural writers to work done with stones which are quarried in thin pieces, such as the Horsham sandstone, Yorkshire stone, the slate stones, &c.; but this is more properly flag or slab work. By rag-stone, near London, is meant an excellent material from the neighbourhood of Maidstone. It is a very hard limestone of bluish-grey colour, and peculiarly suited for medieval work. It is often laid as uncoursed work, or random work (see Random), sometimes as random coursed work and sometimes as regular ashlar. The first method, however, is the more picturesque. (See MASONRY.)
RAGUSA

RAGUSA (Serbo-Croatian Dubrovnik), an episcopal city, and the centre of an administrative district in Dalmatia, Austria. Pop. (1900) of town and commune, 13,174, including a garrison of 1,122. Its situation and its undisturbed atmosphere of antiquity combine to make Ragusa by far the most picturesque city on the Dalmatian coast. It occupies a ridge or promontory, which juts out into the Adriatic Sea, under the bare limestone mass of Monte Sergio. Its seaward fortifications rise directly from the water's edge, one fort, on the north mole, standing boldly on a tall rock almost isolated by a little inlet of the Adriatic. On the landward side a massive round tower dominates the city from a still higher eminence. Beyond the walls and the deep moat, especially on the northward side towards the port of Gravosa, are many pleasant villas, surrounded by gardens in which the aloe, palm and cypress are conspicuous among a number of flowering trees and shrubs. The island of Larcorna lies less than half a mile to the south. Between the seaward ridge and the mountain, the Stradone, or main street, runs along a narrow valley which, until the 13th century, was a marshy channel, dividing the Latin island of Ragusa from the Slavonic settlement of Dubrovnik, on the lower slopes of Monte Sergio. Parallel to the Stradone, on the north, is the Prijeki, a long, very narrow street, flanked by tall houses with overhanging balconies, and greatly resembling a Venetian alley. Despite the havoc wrought by earthquake in 1667, the whole city is rich in antiquarian interest. It possesses one church, of the Byzantine period, which is mentioned in 13th-century documents as even then of great age. Two stately convents of the 14th century stand at the ends of the city; for the Franciscans were set to guard the western gate, or Porta Pile, against the hostile Slavs, while the Dominicans kept the eastern gate, or Porta Place. The Franciscan cloister is a fine specimen of late Romanesque, that of the Dominicans is hardly inferior, though of later date. The Dominican church is approached by a sloping flagged lane, having on one side a beautifully ornamented balustrade of the 18th century. Another 14th-century building is the Sponza, or custom-house, from which the state derived its principal revenue. A fountain and a curious clock-tower in the Piazza, which terminates the Stradone towards the east, were erected by Onofrio, the architect and engineer whose aqueduct, built about 1440, supplied Ragusa with water from the neighbouring hills. The Rector's Palace, another noteworthy example of late Romanesque, combined with Venetian Gothic, is one of the masterpieces of Dalmatian architecture. It has a fine façade of six arches, and the capitals of the supporting pillars are very curiously carved. Especially interesting is the figure of Aesculapius, whose traditional birthplace was Epidaurum or Epidaurus, the parent city of Ragusa. The cathedral dates from the 18th century; and to the same period belongs another church, rebuilt after a fire, but originally erected as a votive offering after the pestilence of 1348, and dedicated to San Biagio (St Blaise), the patron of Ragusa, whose name and effigy continually appear on coins and buildings. Among many fine pieces of jewellers' work preserved in the ecclesiastical treasures may be mentioned the silver statuette of San Biagio, and the reliquary which contains his skull—a 17th-century casket in filigree and enamels with Byzantine medallions of the 11th or 12th century.

The harbour of Ragusa, once one of the chief ports of southern Europe, is too small for modern needs; but Gravosa (Gračë), a village at the mouth of the river Ombra, on the north coast of the island, is still connected by rail with Hercegkova and the Bocche di Cattaro. Ragusa has thus some transit trade with the interior. Its industries include the manufacture of liqueurs, oil, silk and leather; but Malmsey, its famous wine, could no longer be produced after the vine-disease of 1852.

History.—The name Ragusa is of uncertain origin. Constantine Porphyrogenitus, in the 10th century, connects its early form, Lausa, with λαύς, a "precipice." Jireček dissents from this view, and from the common opinion that Dubrovnik is derived from the Slavonic dubrov, "woody." The city first became prominent during the 7th century. In 659 and 656 the flourishing Latin communities of Salona and Epidaurum were destroyed by the Avars, and the island rock of Ragusa was colonized by the survivors. Tradition identifies Epidaurum, whence the majority came, with the neighbouring village of Ragusavecchia; but some historians, including Gelcich, place it on the shores of the Bocche di Cattaro. Both sites show signs of Roman occupation. A colony of Slavs soon joined the Latin settlers at Ragusa, and thus, from an early date, the city formed a link between two great civilizations (see VLACHS). In the 9th century it is said to have repulsed the Saracens; in the 10th it defended itself against the Narentine pirates, and Simeon, tsar of the Bulgarians. Some writers consider that it submitted to Venice in 908, with the rest of Dalmatia; but this is generally denied by the native historians.

During the 11th century an enforced alliance with the Normans drew the republic into war with Venice and Byzantium; and in the 12th century it was attacked by the Bosnians and Serbs. From 1205 to 1258 it acknowledged Venetian suzerainty; its chief magistrate was the Venetian count; and its archbishops, who wielded much political influence, were often Venetian nominees. The constitution took shape during this period, and the first statute-book was published in 1272. Only patricians could hold office in the senate, grand council and lesser council, three bodies which shared the work of government with the count, or, after 1358, the rector. The ancient popular assembly was almost obsolete before the 14th century. Ragusan policy was usually peaceful, and disputes with other nations were frequently arranged by a system of arbitration called stanticum. To refugees of all nations, even to those who had been its own bitter foes, the city afforded asylum; and by means of treaty and tribute it worked its way to a position of mercantile power which Europe could hardly parallel. It was conveniently situated at the seaward end of a great trade route, which bifurcated at Plevlje to Byzantium and the Danube. A compact with the Turks, made in 1370 and renewed in the next century, saved Ragusa from the fate of its more powerful neighbours, Servia and Byzantium, besides enabling the Ragusan caravans to penetrate into Hungary, Croatia, Bosnia, Servia, Bulgaria and Rumania. From 1358 to 1526 the republic was a vassal state of Hungary, and no longer controlled by its greatest commercial rival. It acquired, among other territories, the important ship-building and salt-producing centre Stagno Grande (Ston Veči), on the promontory of Sabbioncello; and from 1413 to 1416 it held the islands of Vis and Cur, near the coast of Cattaro. Meanwhile Ragusan vessels were known not only in Italy, Sicily, Spain, Greece, the Levant and Egypt, but in the more northern parts of Europe. The English language retains in the word "argosy" a reminiscence of the caravans of Ragusa, long known to Englishmen as Argoue, Argoua or Aragosa. In the 16th century the Ragusan merchants went even to India and America, but they were unable to compete with their rivals from western Europe. Many of their seamen took service with Spain; and twelve of their finest ships were lost with the Invincible Armada in 1588. After 1526 the downfall of Hungary left Ragusa free; and about this time a great development of art and literature, begun in the 15th century and continued into the 17th, earned for the city the title of the "South Slavonic Athens." (See SERVIA, LITERATURE.) The earthquake of 1667, which had been preceded by lesser shocks in 1550, 1521, 1556 and 1630, destroyed a considerable portion of the city, and killed about one-fifth of the inhabitants. Only during the Napoleonic wars did the republic regain its prosperity. From 1800 to 1805 it was the sole Mediterranean state remaining neutral, and thus it secured a very large share of the carrying trade. In 1805, however, it was seized by the French; Napoleon deprived it of independence; and in 1814 it was annexed to Austria.

See L. Villari, The Republic of Ragusa (London, 1904), for a thorough description and history, with a full bibliography. T. G.
Jackson, Dalmatia, the Quarnaro and Istriis (Oxford, 1887), gives the best account of Ragusian architecture and antiquities. The most accurate native history is G. Gelich (Gelíc), Dello Stabilimento civile di Ragusa (Ragusa, 1884). The course of Ragusan trade may be studied in G. J. Jellinek, Die Handelsstreitquellen und Berge der Serbien, etc. (Prague, 1879); and Heyd, Geschichte des Handels der Levant am moyen âge (Leipzig, 1885).

RAGUSA, a town of Sicily in the province of Syracuse, 70 m. S.W. of Syracuse by rail and 32 m. direct. It consists of an upper (Ragusa Superiore) and a lower town (Ragusa Inferiore), each of which forms a separate commune. Pop. (1906) of the former, 35,539; of the latter, 866. It has some churches with fine Gothic architecture, and is commercially of some importance, a stone impregnated with bitumen being quarried and prepared for use for paving slabs by being exposed to the action of fire. On the hill occupied by the castle of Ragusa Inferiore stood the ancient Hypia Heraea, a Sicel town, under the walls of which Hippocrates of Gela fell in 401 B.C. A Greek settlement seems to have been in the neighbourhood close to the present railway station, about the middle of the 6th century B.C., and to have disappeared at the end of the 5th. Orsi points out that the remains (cuttings in the rock and a part of the castle wall), attributed by Freeman (History of Sicily, i. 163) to Sicel times, are in reality post-Roman. See Orsi in Notizie degli scavi (1899), 402-418.

RAHWAY, a city of Union county, New Jersey, U.S.A., in the north-eastern part of the state, on the Rahway river and about 20 m. S.W. of New York City. Pop. (1890) 7105; (1900) 7035, of whom 1345 were foreign-born; (1910 U.S. census) 9337. Rahway is served by the main line of the Pennsylvania railroad, and is connected with neighbouring cities by electric lines. It has wide streets and attractive parks, and is, to some extent, a residential suburb of New York and other neighbouring cities. It has a public library (1864), with upwards of 17,000 volumes, and about 13 m. distant is the New Jersey Reformatory (1903), to which prisoners between the ages of sixteen and thirty may be sentenced instead of to the State Prison. There are various manufactures. Rahway was first settled in 1720, and was named in honour of the Indian chief Rahawk, whose tribe owned the site and the surrounding territory; it was chartered as a city in 1858. For many years Rahway was popularly known as Spanktown, and in January 1777, during the War of Independence, a skirmish, known as the battle of Spanktown, was fought here.

RAICHUR, a town of India, in the state of Hyderabad, at the junction of the Madras and Great Indian Peninsula railways, 351 m. N.E. from Madras. Pop. (1901) 22,165. It gives its name to the doab, or tract between the rivers Kistna and Tungabhadra, which was the scene of much fighting between Mahommedans and Hindus as debatable land during the 16th century. It contains a well-preserved fort and two old mosques. It is a thriving centre of trade, with several cotton-presses.

RAID, in the language of international law, an invasion by armed forces, unauthorized and unrecognized by any state, of the territory of a state which is at peace. Piracy is the attack on the high seas or on any vessel by an armed vessel, not recognized as belonging to any state, for the purpose of robbery. A raid for the purpose of carrying off movable property and converting it to the use of the captors would still be distinguishable from piracy, because it was committed on territory subject to an exclusive territorial jurisdiction. Where the attack or invasion by an armed ship not authorized or recognized by any state is not for the purpose of capturing property, it is properly speaking a raid and not piracy. An attack though in time of peace, by armed forces authorized or recognized by a regular government, is not a raid but an act of war, there being a government responsible for the act committed. The fact of any act being authorized, not by the supreme government, but by a chartered company, or by its governing officer, makes no difference in international law, the directorate of a chartered company exercising its powers by delegation of the state under which it holds its charter. The acts of its armed forces cannot in reason be distinguished from the acts of the armed forces of the state government. Thus compensation is just as much due for them as for the deliberate acts of the state itself, and any claim of an injured state can only be preferred against the state to which the company belongs. Invasion by the regular forces of a state, or by the regular forces of its delegated authority, being an act of war, the laws of war apply to it, and, on capture, such forces, or any members or part of such forces, are prisoners of war. On the other hand, the state whose subordinate authorities commit acts of war against a friendly state has the option of following them up as a commencement of hostilities, or of giving satisfactory compensation to the invaded state. Where the invasion is not by forces subject to the orders of a state, the invaded state has the right to apply its own laws for the repression of disturbances in its territory. Thus, in the so-called Jameson Raid, the Transvaal government had no right to treat Dr Jameson, an officer holding his powers under the British government, and his subordinates, as outlaws, and it was probably so advised, and the British government prepared proper compensation for an act for the consequences of which, under international law, it was responsible.

British domestic law punishes raiding under the Foreign Enlistment Act 1870 (33 & 34 Vict. c. 90). Section 11 of this act provides as follows:—"If any person within the limits of His Majesty's dominions, and without the licence of His Majesty, prepares or fits out any naval or military expedition to proceed against the dominions of any friendly state, the following consequences shall ensue: (1) Every person engaged in such preparation or fitting out, or assisting therein, or employed in any capacity in such expedition, shall be guilty of an offence against this act, and shall be punishable by fine and imprisonment or either of such punishments, at the discretion of the Court before which the offender is convicted; and imprisonment, if awarded, may be either with or without hard labour. (2) All ships and their equipments, and all arms and munitions of war, used in or forming part of such expedition, shall be forfeited by His Majesty." A proviso for the punishment of accessories as principal offenders, and section 13 limits the term of imprisonment for any offence under the act to two years. In the Sandowal case (1886), in which Colonel Sandowal, who was not a British subject, bought guns and ammunition and shipped them to Antwerp, where they were put on board a vessel, which afterwards made an attack on Venezuela, it was held that the offence of fitting out and preparing an expedition within British territory against a friendly state, under this section, is sufficiently constituted by the purchase of guns and ammunition in the British Empire, and their shipment for the purpose of being put on board a ship in a foreign port, with knowledge of the purchaser and shipper that they are to be used in a hostile demonstration against such state, though the shipper takes no part in any overt act of war, and the ship is not fully equipped for the expedition within any British port. Under the same section, Dr Jameson, administrator of the British South Africa Company, and his confederates were convicted in the Criminal Court and sentenced to different terms of imprisonment. The offence committed under a British act is, of course, that of preparing and fitting out an expedition on British territory. Any acts subsequently committed by any British expedition on foreign soil are beyond the operation of domestic legislation, and fail to be dealt with by the domestic legislation of the state within which they occur, or by diplomacy, as the case may be. (T.B.A.)

RAIFFEISEN, FRIEDRICH WILHELM (1818-1888), founder of the German system of agricultural co-operative banks, was

1 The preamble to the Foreign Enlistment Act 1870 stated that its object was "to make provision for the regulation of the conduct of Her Majesty's subjects during the existence of hostilities between foreign states with which Her Majesty is at peace." This preamble was repealed by the Statutes Law Revision (No. 2) Act 1893.
2 R. V. Sandowal, 1886, 56 Law Times, 526.
born at Hamm on the 30th of March 1818, being the son of Gottfried Raiffeisen, burgomaster of that place. Educated privately, he entered the artillery in Cologne, but defective eyesight compelled him to leave the army. He then entered the public service at Coblenz, and in 1848 he was appointed burgomaster of Weyerbusch. Here he was so successful that in 1848 he was transferred to a life capacity to Flammersfeld, and in 1852 to Heddersdorf. Raiffeisen devoted himself to the improvement of the social condition of the cultivators of the soil, and did good work in the planning of public roads and in other ways. The distress of the years 1846–47, the causes of which he discerned in the slight amount of credit obtainable by the small landed proprietors, led him to seek for a remedy in co-operation, and at Heddersdorf and at Weyerbusch he founded the first agricultural co-operative loan banks (Darlehnskassenverein). These banks were called after him, and their foundation resulted in a widespread system of land banks, supported by the government. In 1865 the state of his health compelled him to retire, but he continued to take an interest in the movement he had originated, and in 1878 he founded at Newi, in a periodical, Das landwirtschaftliche Genossenschaftsblatt. He died on the 11th of March 1888.

Among Raiffeisen's writings are, Die Darlehnskassenvereine als Mittel zur Ablösung (Newiued, 1866; new ed., 1887); Anleitung zur Geschäfts- und Buchführung ländlicher Spar- und Darlehnskassenvereine (new ed., 1896); and Kurze Anleitung zur Gründung von Darlehnskassen (new ed., 1898). See also: Friedrich Wilhelm Raiffeisen (1890); H. W. Wolff, People's Banks. A Record of Social and Economic Success (1895); and Fassbender, Friedrich Wilhelm Raiffeisen (Berlin, 1902).

RAIGARH, a feudatory state of India, in the Chattisgarh division of the Central Provinces. Area, 1486 sq. m. Pop. (1901) 174,929, showing an increase of 4% in the decade. Estimated revenue, £19,000; tribute, £260. The chief belongs to the old Gond royal family. The state is traversed by the Bengal-Nagpur railway, with a station at Raigah town, 365 m. from Calcutta. Rice is the chief crop; iron ore is worked by indigenous methods, and coal is known to exist. Fine tussore silk is produced at Raigah town (pop. 6764). Raigah is also the site of a hill fortress in the Kolakia district, Bombay, which Sidavi made his chief place of residence. Here he was crowned in 1674.

RAIKES, ROBERT (1735-1811), English educationist, the founder of Sunday schools, was the son of Robert Raikes, a printer in Gloucester and proprietor of the Gloucester Journal, and was born on the 14th of September 1735. On the death of his father in 1757 he succeeded him in the business, which he continued to conduct till 1760. Along with some others he started a Sunday school at Gloucester in 1780, and on his giving publicity to the enterprise in the columns of his journal the notice was copied into the London papers and awakened considerable attention. For nearly thirty years he continued actively engaged in the promotion of his undertaking, and he lived to witness its wide extension throughout England. He died on the 5th of April 1811. His statue stands on the Thames Embankment.

Several various accounts of the life and work of Raikes mention may be made of that by P. M. Eastman, 1880.

RAIL (1) (From Fr. Râle, cf. Ger. Ralle, Low Lat. Rallus, of unknown origin), originally the English name of two birds, distinguished from one another by a prefix as land-rail and water-rail, but latterly applied in a much wider sense to all the species which are included in the family Rallidae.

The land-rail, also very commonly, known as the corn-rail, and sometimes as the daker-hen, is the Rallus crex of Linnaeus and Crex pratensis of recent authors. Its monotonous grating cry has given it its common name in several languages. With comparatively few individuals exceptions, the land-rail is essentially migratory. It is the Ortygometra of classical authors—supposed by them to lead the quail (q.v.) on its voyages—and in the course of its wanderings has now been known to reach the coast of Greenland, and several times that of North America, to say nothing of Bermuda, in every instance we may believe as a straggler from Europe or Barbary.

The land-rail looks about as big as a partridge, but on examination its appearance is found to be very deceptive, and it will hardly ever weigh more than half as much. The plumage above is of a tawny brown, the feathers being longitudinally streaked with blackish brown; beneath it is of a yellowish white; but the flanks are of a light chestnut barred with white. The species is very locally distributed, and in a way for which there is at present no accounting. In some dry upland and corn-growing districts it is plentiful; in others, of apparently the same character, it but rarely occurs; and the same may be said in regard to low-lying marshy meadows, in most of which it is in season always to be heard, while in others having a close resemblance to them it is never met with. The nest is on the ground, generally in long grass, and therein from nine to eleven eggs are commonly laid. These are of a cream-colour, spotted and blotched with light red and grey. The young when hatched are thickly clothed with black down, as is the case in nearly all species of the family.

The water-rail, locally known as the skiddy or billcock, is the Rallus aquaticus of ornithology, and seems to be less abundant than the preceding, though that in some measure due to its frequenting places into which from their swampy nature men do not often intrude. Having a general resemblance to the land-rail, it can be in a moment distinguished by its partly red and much longer bill, and the darker coloration of its plumage—the upper parts being of an olive brown with black streaks, the breast and belly of a sooty grey, and the flanks dull black barred with white. Its geographical distribution is very wide, extending from Iceland (where it is said to preserve its existence during winter by resorting to the hot springs) to China; and though it inhabits Northern India, Lower Egypt and Barbary, it seems to pass beyond the tropical line. It never affects upland districts as does the land-rail, but always haunts wet marshes or the close vicinity of water. Its love-note is a loud and harsh cry, not continuous, repeated as is that of the land-rail, but uttered at considerable intervals and so suddenly as to have been termed "explosive." Besides this, which is peculiar to the cock-bird, it has a croaking call that is frog-like. The eggs resemble those of the preceding, but are more brightly and delicately tinted.

The various species of rails, whether allied to the former or latter of those just mentioned, are far too numerous to be here noticed. Hardly any part of the world is without a representative of the genera Crex or Rallus, and every considerable country has one or perhaps more of each—though it has been the habit of systematists to regard them as minor species of Raia, which are generally much confused with difficulty. Thus in Europe alone three other species allied to Crex pratensis occur more or less abundantly; but one of them, the spotted rail or crake, has been made the type of a so-called genus Pорzana, and the other two, little birds not much bigger than larks, are considered to form a genus Зейпóрния. The first of these, which used not to be uncommon in the eastern part of England, has a very near representative in the Carolina rail or карис (Porzana carolina), a small bird of North America, often there miscalled the ortolan, just as its European analogue, C. porzana, is in England often termed the dotterel. But, passing over these as well as some belonging to genera that can be much better defined, and others in a large number of terms of Raia, Spargya, coot (q.v.), moor-hen (q.v.) and ocydrome (q.v.), a few words must be said of the more distant group formed by the South American Helornis, and the African and Indian Podiceps, comprising four or five species. For, in 1838, it was shown by Sir Edward R. Bowdler, 2nd earl, in the neighbourhood of the rails, but is now associated as a sub-order mezidae with Galliform birds. On the other hand the jacanas or farria, which from their long toes were once thought to belong

1 Formerly it seems to have been a popular belief in England that the land-rail in autumn transformed itself into a water-rail, resuming its own characters in spring.
to the rails, are now generally admitted to be Linicolene, while the genus Aramus—the cousin or limbkin of the southern United States—still occupies a very undetermined position. (A. N.)

(2) Through O.Fr. *raille*, from Lat. *regula*, a rule; the Du. and Swed. *regel*, Ger. *Riegel*, bolt or bar, are probably also from the Latin), a horizontal bar of wood, metal or other material resting on, or fixed in, upright posts to form a fence, or as a support for hanging things on, to form the "hand-rail" of a stair, &c.; on a ship the upper part of the bulwarks, e.g. the "taftail," round the stern bulwarks; especially, one of the pair of iron or steel bars on which a train or tram runs (see RAILWAYS).

There are two other words "rail": (a) an obsolete word, O.E. *rhegel*, for a stile; then in the contemptuous "night-rail"; (b) a verb, to abuse, use angry language, from Fr. *ralier*, possibly from the same root as Lat. *radere*, to scrape. The word is also seen in "rally," to banter, tease (distinguish, however, "rally," to bring together, especially of defeated troops (from Fr. *ralier*, re, again, and *alter*, ally, Lat. *altigere*).

**RAILWAYS.** Railways had their origin in the tramways (g.v.) or wagon-ways which at least as early as the middle of the 16th century were used in the mineral districts of England round Newcastle for the conveyance of coal from the pits to the river Tyne for shipment. It may be supposed that originally the public roads, when worn by the cartage of the coal, were repaired by laying planks of timber at the bottom of the ruts, and that then the planks were laid on the surface of special roads or ways^1^ formed between the collieries and the river.

"The manner of the carriage," says Lord Keeper North in 1676, "is by laying rails of timber . . . exactly straight and parallel, and bulky cartage made with four rowlets fitting these rails, whereby the carriage is so easy that one horse will draw down four or five chaldrons of coal" (from 9 to 13 2 tons). The planks were of wood, often beech, a few inches wide, and were fastened down, end to end, on logs of wood, or "sleepers," placed crosswise at intervals of two or three feet. In time it became a common practice to cover them with a thin sheathing or plating of iron, in order to add to their life; this expedient caused more wear on the wooden rollers of the wagons, and, apparently towards the middle of the 18th century, led to the introduction of iron wheels, the use of which is recorded on a wooden railway near Bath in 1734. But the iron sheathing was not strong enough to resist buckling under the passage of the loaded wagons, and to remedy this defect the plan was tried of making the rails wholly of iron. In 1767 the Colebrookdale Iron Works cast a batch of iron rails or plates, each 3 ft. long and 4 in. broad, having at the inner side an upright ledge or flange, 3 in. high; these being cast in pairs into a mould and afterwards riveted together, and to this end 2 1/2 in. at the ends, for the purpose of keeping the flat wheels on the track. Subsequently, to increase the strength, a similar flange was added below the rail. Wooden sleepers continued to be used, the rails being secured by spikes passing through the extremities, but about 1793 stone blocks also began to be employed—an innovation associated with the name of Benjamin Outram, who, however, first, apparently was not actually the first to make it. This type of rail (fig. 1) was known as the plate-rail, tramway-plate or barrow-way-plate—names which are preserved in the modern term "platerayer" applied to the men who lay and maintain the permanent way of a railway.

Another form of rail, distinguished as the edge-rail, was first used on a line which was opened between Loughborough and Nanpantan in 1789. This line was originally designed as a "plate-way" on the Outram system, but objections were raised to rails with upstanding ledges or flanges being laid on the turnpike road which was crossed at Loughborough on the level. In other cases this difficulty was overcome by paving or "causewaying" the road up to the level of the top of the flanges, but

^1^ Another thing that is remarkable is their way-leaves: for, when men have pieces of ground between the colliery and the river, they sell leave to lead coals over their ground" (Roger North).

on this occasion William Jessop, of the Butterley Iron Works, near Derby, proposed to get over it by laying down two plates of iron, perfectly flat and level with the road but each having on its outside a groove 3/4 in. wide and 1/2 in. deep to control extra guiding wheels which were to be of somewhat larger diameter than the bearing wheels and to be affixed to them. The rest of the line was laid with what were substantially plate-rails placed on their edge instead of flat. These were cast in 3 ft. lengths, of a double-flanged section, and for the sake of strength they were "fish-bellied" or deeper in the middle than at the ends. At one end of each rail the flange spread out to form a foot which rested on a cross sleeper, being secured to the latter by a spike passing through a central hole, and above this foot the rail was so shaped as to form a socket into which was fitted the end of the next rail. Each length was thus fastened to a sleeper at one end, while at the other it was socketed into the end of its fellow. This method, however, was not found satisfactory: the projecting feet were liable to be broken off, and in 1799 or 1800 Jessop abandoned them, using instead separate cast-iron sockets or chairs, which were fastened to the sleepers and in which the rails were supported in an upright position. In the first instance he proposed to place the guiding wheels outside the bearing wheels, and the Nanpantan line was laid on this plan with a width of 5 ft. between the guide wheels; but before it was opened he decided not only to cast the guiding wheels and bearing wheels in one piece but also to put the former inside the rails, arguing that with this arrangement the edge-rails themselves would keep the wheels in position on the axles, whereas with that first contemplated fastenings would have been required for them (fig. 2). Jessop thus produced what was virtually the flanged wheel of to-day, having the flanges inside the rails, and further, it is said, established what has become the standard gauge of the world, 4 ft. 8 1/2 in., or 5 ft. minus the width of two of his rails.

These two systems of constructing railways—the plate-rail and the edge-rail—continued to exist side by side until well on in the 19th century. In most parts of England the plate-rail was preferred, and it was used on the Surrey iron railway, from Wandsworth to Croydon, which, sanctioned by parliament in 1801, was finished in 1803, and was the first railway available to the public on payment of tolls, previous lines having all been private and reserved exclusively for the use of their owners.

In South Wales again, where in 1811 the railways in connexion with canals, collieries and iron and copper works had a total length of nearly 130 miles, the plate-way was almost universal. But in the north of England and in Scotland the edge-rail was held in greater favour, and by the third decade of the century its superiority was generally established. The manufacture of the rails themselves was gradually improved. By making them in longer lengths a reduction was effected in the number of joints—always the weakest part of the line; and another advance consisted in the substitution of wrought iron for cast iron, though that material did not gain wide adoption until after the patent for an improved method of rolling rails granted in 1820 to John Birkshaw, of the Bedlington Ironworks, Durham. His rails were wedge-shaped in section, much wider at the top than at the bottom, with the intermediate portion or web thinner still, and he recommended that they should be made 18 ft. long, even suggesting that several of them might be welded together to end in forming considerable lengths. They were supported on sleepers by chairs at intervals of 3 ft., and were fish-bellied between the points of support. As used by George Stephenson on the Stockton & Darlington and Whitstable & Canterbury lines they weighed 28 lb per yard. On the Liverpool & Manchester railway they were usually 12 ft. or 15 ft. long and weighed 35 lb to the yard, and they were fastened by iron wedges to chairs weighing 15 or 17 lb each. The chairs were
in turn fixed to the sleepers by two iron spikes, half-round wooden cross sleepers being employed on embankments and stone blocks 20 in. square by 10 in. deep in cuttings. The fish-bellied rails, however, were found to be short and, from 1834 they began to be replaced with parallel rails weighing 50 lb to the yard.

The next important development in rail design originated in America, which, for the few lines that had been laid up to 1830, remained content with wooden bars faced with iron. In that year Robert Livingston Stevens (1787–1856), devised for the Camden & Amboy railway a rail similar to its top to those in use in England, but having a flat base or foot by which it was secured to the sleepers by hook-headed spikes, without chairs (fig. 3); he had to get the first lot of these rails, which were 15 ft. long and weighed 36 lb to the yard, manufactured in England, since there were then no mills in America able to roll them. This type, which is often known as the Vignoles rail, after Charles Blacker Vignoles (1793–1873), who re-invented it in England in 1836, is in general use in America and on the continent of Europe. The bridge-rail (fig. 4)—so called because it was first laid on bridges—was supported on continuous longitudinal sleepers and held down by bolts passing through the flanges, and was employed by J. K. Brunel on the Great Western railway, where, however, it was abandoned after the line was converted from broad to standard gauge in 1842. In the double-headed rail (fig. 5), originated by Joseph Locke in 1837, and first laid on the Grand Junction railway, the two rails were equal. This rail was more easily rolled than others, and, being reversible, was in fact two rails in one. But as it was laid in cast-iron chairs the lower table was exposed to damage under the hammering of the traffic, and thus was liable to be rendered useless as a running surface. In consequence the bull-headed rail (fig. 6) was evolved, in which the lower table was made of smaller size and was intended merely as a support, not as a surface to be used by the wheels. There was a waste of metal in these early rails owing to the excessive thickness of the vertical web, and subsequent improvements have consisted in adjusting the dimensions so as to combine strength with economy of metal, as well as in the substitution of steel for wrought iron (after the introduction of the Bessemer process) and in minute attention to the composition of the steel employed.

It was found, naturally, that the rails would not rest in their chairs at the joints, but were loosened and bruised at the ends by the blows of the traffic. The fish-joint was therefore devised in 1847 by W. Bridges Adams, the intention being by "fishing" the joints to convert the rails into continuous beams. In the original design two chairs were placed, one under each rail, a few inches apart, as in fig. 7. The joint was thus suspended between the two chairs, and two keys of iron, called "fishes," fitting the side channels of the rails, were driven in on each side between the chairs and the rails. In subsequent modifications the fishes were, as they continue to be, bolted to and through the rails, the sleepers being placed rather further apart and the joint being generally suspended between them.

The iron tramway or railway had been known for half a century and had come into considerable use in connexion with collieries and quarries before it was realized that for the carriage of general merchandise it might prove a serious competitor to the canals, of which a large mileage had been constructed in Great Britain during that period. In the article on "Railways" in the Supplement to the Encyclopaedia Britannica, published in 1824, it is said: "It will appear that this species of inland carriage [railways] is principally applicable where trade is considerable and the length of conveyance short; and is chiefly useful, therefore, in transporting the mineral produce of the kingdom from the mines to the nearest land or water communication, whether sea, river or canal. Attempts have been made to bring it into more general use, but without success; and it is only in particular circumstances that navigation, with the aid of locks or inclined planes to surmount the elevations, will not present a more convenient medium for an extended trade." It must be remembered, however, that at this time the railways were nearly all worked by horse-traction, and that the use of steam had made but little progress. Richard Trevithick, indeed, had in 1804 tried a high-pressure steam locomotive, with smooth wheels, on a plate-way near Merthyr Tydvil, but it was found more expensive than horses; John Blenkinsop in 1811 patented an engine with caged wheel and rack-rail which was used, with commercial success, to convey coal from his Middleton colliery to Leeds; William Hedley in 1813 built two locomotives—Puffing Billy and Wylam Dilly—for hauling coal from Wylam Colliery, near Newcastle; and in the following year George Stephenson's first engine, the Blucher, drew a train of eight loaded wagons, weighing 30 tons, at a speed of 4 m. an hour up a gradient of 1 in 450. But, in the words of the same article, "This application of steam has not yet arrived at such perfection as to have brought it into general use."

The steam locomotive, however, and with it the railways, soon began to make rapid progress. On the Stockton & Darlington railway, which was authorized by parliament in 1825, animal power was at first proposed, but on the advice of Stephenson, its engine, steam-engines were adopted. This line, with three branches, was over 38 m. in length, and was in the first instance laid with a single track, passing places being provided at intervals of a quarter of a mile. At its opening, on the 27th of September 1825, a train of thirty-four vehicles, making a gross load of about 90 tons, was drawn by one engine driven by Stephenson, with a signalman on horse-back in advance. The train moved off at the rate of from 10 to 12 m. an hour, and attained a speed of 15 m. an hour on favourable parts of the line. A train weighing 92 tons could be drawn by one engine at the rate of 5 m. an hour. The principal business of the new railway was the conveyance of minerals and goods, and from the first passengers insisted upon being carried, and on the 10th of October 1825 the company began to run a daily coach, called the "Experiment," to carry six inside, and from fifteen to twenty outside, making the journey from Darlington to Stockton and back in two hours. The fare was 1s., and each passenger was allowed to take baggage not exceeding 14 lb weight. The rate for carriage of merchandise was reduced from 5d. to one-fifth of a penny per ton per mile, and that of minerals from 7d. to 1½d. per ton per mile. The price of coals at Darlington fell from 18s. to 8s. 6d. a ton.

The example of the Stockton & Darlington line was followed by the Monklands railway in Scotland, opened in 1826, and several other small lines—including the Canterbury &
INTRODUCTORY

RAILWAYS

Whistable, worked partly by fixed engines and partly by locomotives—quickly adopted steam traction. But the Liverpool & Manchester railway, opened in 1829, first impressed the national mind with the fact that a revolution in the methods of travelling had really taken place; and further, it was for it that the first high-speed locomotive of the modern type was invented and constructed. The directors having offered a prize of £500 for the best engine, trials were held on a finished portion of the line at Rainhill in October 1829, and three engines took part—the Rocket of George and Robert Stephenson, the Novelty of John Braithwaite and John Ericson, and the Sanspareil of Timothy Hackworth. The last two of these engines broke down under trial, but the Rocket fulfilled the conditions and won the prize. Its two steam cylinders were 8 in. in diameter, with a stroke of 16½ in., and the driving wheels, which were placed in front under the funnel, were 4 ft. 8½ in. in diameter. The engine weighed 44 tons; the tender following it, 3 tons 4 cwt.; and the iron carriages drawn by it on the trial, 9 tons 11 cwt.: thus the weight drawn was 125 tons, and the gross total of the train 17 tons. The boiler evaporated 185 cub. ft., or 114 gals., of water an hour, and the steam pressure was 50 lb per square inch. The engine drew a train weighing 13 tons 35 cwt. in 48 minutes, the rate being thus nearly 44 m. an hour; subsequently it drew an average gross load of 40 tons behind the tender at 13½ m. an hour. The Rocket possessed the three elements of efficiency of the modern locomotive—the internal water-surrounded fire-box and the multitubular flue in the boiler; the blast-pipe, by which the steam after doing its work in the cylinders was exhausted up the chimney, and thus served to increase the draught and promote the rapid combustion of the fuel; and the direct connexion of the steam cylinders, one on each side of the engine, with the two driving wheels mounted on one axle. Of these features, the blast-pipe had been employed by Trevithick on his engine of 1804, and direct driving without intermediate gearing had been adopted in several previous engines; but the use of a number (25) of small tubes in place of one or two large flues was an innovation which in conjunction with the blast-pipe contributed greatly to the efficiency of the engine. After the success of the Rocket, the Stephensons received orders to build seven more engines, which were of very similar design, though rather larger, being four-wheeled engines, with the two driving wheels in front and the cylinders behind; and in October 1830 they constructed a ninth engine, the Planet, also for the Liverpool & Manchester railway, which still more closely resembled the modern type, since the driving wheels were placed at the fire-box end, while the two cylinders were arranged under the smoke-box, inside the frames. The main features of the steam locomotive were thus established, and its subsequent development is chiefly a history of gradual increase in size and power, and of improvement in design, in material and in mechanical construction, tending to increased efficiency and economy of operation.

In America the development of the locomotive dates from almost the same time as in England. The earliest examples used in that country, apart from a small experimental model constructed by Peter Cooper, came from England. In 1828, on behalf of the Delaware & Hudson Canal Company, which had determined to build a line, 16 m. long, from Carbondale to Honesdale, Pennsylvania, Horatio Allen ordered three locomotives from Messrs Foster & Rastrick, of Stourbridge, and one from George Stephenson. The latter, named the America, was the first to be delivered, reaching New York in January 1829, but one of the others, the Stourbridge Lion, was actually the first practical steam locomotive to run in America, which it did on the 4th of August 1829. The first American-built locomotive, the Best Friend, of Charleston, was built by the New Point Foundry, New York, in 1830, and was put to work on the South Carolina railroad in that year. It had a vertical boiler, and was carried on four wheels all coupled, the two cylinders being placed in an inclined position and having a bore of about 6 in., with a stroke of 16 in. It is reported to have hauled 40 or 50 passengers in 4 or 5 cars at a speed of 16–21 m. an hour. After a few months of life it was blown up, its attendant, annoyed by the sound of the escaping steam, having fastened down the safety-valve. A second engine, the West Point, also built at West Point Foundry for the South Carolina railroad, differed from the Best Friend in having a horizontal boiler with 6 or 8 tubes, though in other respects it was similar. In 1831 the Baltimore & Ohio Company offered a prize of $4000 for an American engine weighing 33½ tons, able to draw 15 tons at 15 m. an hour on the level: it was won by the York of Messrs Davis & Gartner in the following year. Matthias W. Baldwin, the founder of the famous Baldwin Locomotive Works in Philadelphia, built his first engine, Old Ironsides, for the Philadelphia, Germantown & Morristown railroad; first tried in November 1832, it was modelled on Stephenson's Planet, and had a single pair of driving wheels at the fire-box end and a pair of carrying wheels under the smoke-box. His second engine, the E. L. Miller, delivered to the South Carolina railroad in 1834, presented a feature which has remained characteristic of American locomotives—the front part was supported on a four-wheeled swivelling bogie-truck, a device, however, which had been applied to Puffing Billy in England when it was rebuilt in 1815.

The Liverpool & Manchester line achieved a success which surpassed the anticipations even of its promoters, and in consequence numerous projects were started for the construction of railways in various parts of Great Britain. In the decade following its opening nearly 2000 m. of railway were sanctioned by parliament, including the beginnings of most of the existing trunk-lines, and in 1840 the actual mileage reached 1331 m. The next decade saw the “railway mania.” The amount of capital which parliament authorized railway companies to raise was about 14½ millions on the average of the two years 1842–1843, 17½ millions in 1844, 60 millions in 1845, and 132 millions in 1846, though this last sum was less than a quarter of the capital proposed in the schemes submitted to the Board of Trade; and the wild speculation which occurred in railway shares in 1845 contributed largely to the financial crisis of 1847. In 1850 the mileage was 6635, in 1860 it was 10,410, and in 1870 it was 15,310. The increase in the decade 1860–1870 was thus nearly 50%, but subsequently the rate of increase slackened, and the mileages in 1880, 1890 and 1900 were 17,935, 20,073 and 21,855. In the United States progress was more rapid, for, beginning at 2816 in 1840, the mileage reached 9015 in 1850, 30,600 in 1860, 87,801 in 1880, and 169,604 in 1900. Canada had no railway till 1853, and in South America construction did not begin till about the same time. France and Austria opened their first lines in 1818: Belgium, Germany, Russia, Italy and Holland in the succeeding decade: Switzerland and Denmark in 1844, Spain in 1848, Sweden in 1851, Norway in 1853, and Portugal in 1854; while Turkey and Greece delayed till 1860 and 1866. In Africa Egypt opened her first line (between Alexandria and Cairo) in 1856, and the Cape Colony followed in 1860. In Asia the first line was that between Bombay and Tannah, opened in 1833, and in Australia Victoria began her railway system in 1854 (see also the articles on the various countries for further details about their railways).

Transcontinental Railways.—A railway line across North America was first completed in 1869, when the Union Pacific, building from the Missouri river at Omaha (1400 m. west of New York), met the Central Pacific, which built from San Francisco eastwards, making a line 1848 m. long through a country then for the most part uninhabited. This was followed by the Southern Pacific in 1881, from San Francisco to New Orleans, 2489 miles; the Northern Pacific from St Paul to Seattle, 1573 miles; the Atchison, Topeka & Santa Fé, from Kansas City to San Diego; and the Great Northern from St Paul to Seattle and New Westminster in 1893. Meanwhile the Canadian Pacific, a true transcontinental line, was built from Montreal, on Atlantic tide-water, to the Pacific at Vancouver, 2906 miles. But these lines have been
dwarfed since 1891 by the Siberian railway, built by the Russian government entirely across the continent of Asia (from Chelabinsk (1765 m. by rail east of St Petersburg) to Vladivostok, a distance of 4073 m., with a branch from Khabarin about 500 m. long to Dalny and Port Arthur. The main line was finished in 1902, except for a length of about 170 m. in very difficult country around the south end of Lake Baikal; this was constructed in 1904, communication being maintained in the interval by ferry-boats, which conveyed all the carriages of a train across the lake, more than 40 m., when the ice permitted. A transcontinental line was long ago undertaken across South America from Buenos Aires to Valparaiso, where the continent is only about 900 m. wide. The last section through the Andes was finished in 1910.

**General Statistics**

**Mileage.**—At the close of 1897 there were approximately 601,868 miles of railway in the world, excluding tramways.

On the whole, the best statistical source for this information is the annual computation published by the Archiv für Eisenbahnenwesen, the official organ of the Prussian Ministry of Public Works; but the figure quoted above utilizes the Board of Trade returns for the United Kingdom and the report of the Interstate Commerce Commission for the United States. In the United States and in certain other countries, a fiscal year, ending on the 30th of June or at some other irregular period, is substituted for the calendar year.

The partition of this total between the principal geographical divisions of the world is given in Table I.

In the United States railway mileage now tends to increase at the rate of slightly over 5000 miles a year, which is about 21% on the present main line mileage. In the 'eighties, the country passed through a period of competitive building, which was productive of much financial disaster. Thus, in 1883, 11,599 m. were built—an addition equivalent to more than 11% of the mileage then existing—and in 1887, 12,876 m. were built. Unjustifiable railway expansion had much to do with the American commercial panics of 1884 and 1893. After the reconstruction period of the 1893 panic, however, the tendency for a number of years was to spend larger sums in bettering existing railways rather than in new extensions. The decade from 1896 until 1905, inclusive, saw huge sums spent on yards, passing tracks, grade reduction, elimination of curves, substitute larger locomotives and cars for small ones, &c. During those ten years, the route mileage increased 14,921 m., or 17%, while the mileage of second, third, fourth and yard tracks and sidings increased 32,666 m., or nearly 57%. The number of locomotives increased 12,400, or 35%, and the number of passenger cars 54,522, or 24%. Moreover, the average tractive power per locomotive and the average capacity per freight car advanced greatly in this period, although specific figures cannot be given.

Thus it may fairly be said that the railway system of the United States was reconstructed between 1896 and 1905, so far as concerns rails, sleepers, ballast and the general capacity of a given group of lines to perform work. About 1905, however, a new tendency became apparent. At that time the so-called transcontinental railways, connecting the Pacific coast of the United States with the central portions of the country, and thus with the group of railways reaching the Atlantic seaboard, consisted of five railways within the borders of the United States, and one in Canada. In Canada the Canadian Pacific was the only transcontinental line extending from St John, on the bay of Fundy, and from Quebec, on the river St Lawrence, to Vancouver, on the strait of Georgia, the distance from St John to Vancouver being approximately 3379 m. Within the boundaries of the United States the northernmost of the transcontinental lines was the Great Northern railway, extending from a point opposite Vancouver, B.C., and from Seattle, Wash., to Duluth, on Lake Superior, and to St Paul and Minneapolis, Minn., a connection through Chicago, Minn., was made with another line, the Chicago, Burlington & Quincy, owned jointly by the Great Northern and the Northern Pacific.

Next, south of the Great Northern, lay the Northern Pacific railway, starting on the west from Portland, Ore., and from Seattle and Spenard, Ala., extending east to Detroit, Mich., St Paul and Minneapolis by way of Helena, Mont. The Central Pacific—Union Pacific route to the coast, with its important affiliated companies, the Oregon Short Line and the Oregon Railroad & Navigation Company, extended from San Francisco, Cal., to Tooele, Utah, and from the Pacific to the Missouri River, by way of St. Louis, Mo., and from that river to Omaha, Neb., by way of Salt Lake City; the Atchison, Topeka & Santa Fé extended from San Francisco, and Los Angeles, Cal., to Chicago and to Galveston, Tex.; while the Southern Pacific had its line from San Francisco and Los Angeles to Galveston and New Orleans, running for the greater part of the distance just north of the Mexican border.

Thus it will be observed that the five great cities of the Pacific continent, San Francisco, Seattle, Chicago, St. Louis, and Los Angeles, Cal., were already well supplied with railways; but the growth of the fertile region lying west of the transcontinental divide was most attractive to American railway builders; and railways serving this district, almost all of them in trouble ten years before, were showing gains in earnings. In 1893 the Gould lines determined to enter this Pacific territory. Hitherto the western terminus of this group of lines had been Salt Lake City, Utah; by the exceedingly bold construction of the Western Pacific from San Francisco to Oakland, Cal., opposite San Francisco, and an additional line to the Pacific coast was provided, having low grades and being in all respects well adapted for cheap operation.

Shortly after the plans were announced for building the Western Pacific, in 1893, the Chicago, Milwaukee & St. Paul, extending from Chicago, Ill., in the east, to Portland, Ore., in the west. Before that time the St Paul had been a great local railway, operating primarily in the Dakotas, Minnesota, Iowa, Wisconsin and Illinois; but by the construction of a long arm from the Missouri river to the Pacific Ocean, it became a transcontinental line of the first importance, avoiding the mistakes of earlier railway builders by securing a line with easy gradients through the most favourable regions.

At the same time that these two extensions were being undertaken by well-established railways, a new company—the Kansas City, Mexico & Orient—was engaged in constructing a line almost due south-west from Kansas City, Mo., to the lower part of the gulf of California in Mexico; while an additional independent line was under construction from St Louis, Mo., to Minneapolis, Minn., a north-westerly direction towards the Pacific coast. The guarantee for this activity may be illustrated by a single fact: the combined building operations, in 1908, of San Francisco, Seattle, Portland, Los Angeles, Spokane and Salt Lake City exceeded the combined building operations of Philadelphia, Pittsburg, Kansas City, Boston, Baltimore and Cincinnati during the same year. San Francisco spent more in new permanent structures than Philadelphia, and Seattle spent more than Pittsburg.

**Recent American railway development, viewed in its larger aspects, has thus been characterized by what may be described as the rediscovery of the Pacific coast. How far this movement may go is impossible to say; it is certain, however, that it will be enormously important in re-aligning trade conditions in the United States, Canada and Mexico.**

Table III illustrates the railway mileage in the continent of America at the close of 1907.

Outside the United States and Canada, the most interesting American developments are in Mexico and Argentina, these countries
having nearly the same amount of railway mileage. In Mexico the national government is carrying out a consistent policy of developing its railway lines. It has succeeded in restoring the credit of these enterprises, and is proceeding with care and skill to form the lines into a national transportation system. In Argentina about half of the railways are owned and operated by the government, the balance being in the hands of private companies, largely controlled in England. Development of these lines has been primarily an extension from the large cities in the East to the agricultural districts in the West, but a change of great importance was brought about in 1910 by the completion of the last tunnel on the Argentine Transandine Railway, which serves to connect Santiago, Valparaiso and the other great cities of the west coast with Buenos Aires, Montevideo, Bahia, Rio de Janeiro and the other great cities of the east coast. Naturally the company named does not reach all of these points, but its line across the Andes supplies the indispensable link of communication, in the absence of which the east coast towns and the west coast towns have hitherto been as widely separated as if they had been located on different continents—indeed, far more widely separated in point of time and of freight charges than Great Britain and the United States.

Although more than half of the total mileage of Asia is in British India, it is probable that the greatest proportionate gains in the near future will be in China, Siberia and Manchuria, and Central Russia in Asia. In proportion to its population China has the least railway development of any of the great countries of the world. The probability that its present commercial awakening will extend seems large, and in that case will need a vast increase in its interior communications.

In Africa, it will be seen by Table V. that the railway mileage in the British possessions amounts to almost five-sixths of the total.

The so-called Cape-to-Cairo route shows occasional extensions, particularly in the opening up of new country in Central Africa by the Rhodesian railway system. The Rhodesian railway system in 1910 had penetrated north of Broken Hill, which is just above the fifteenth parallel of south latitude, while the Egyptian railway system had reached Gondokoro, located close to the fifth parallel of north latitude. The intervening distance, through country exceedingly unhealthy for white men, and therefore promising no traffic except raw materials, does not seem a likely field for rapid railway extension.

In Australia the increase in railway mileage in the five years ending December 31st, 1907 was about 7%—a small proportion as compared with America, Asia or Africa. The greatest increase, both relative and absolute, was in Queensland; the smallest in South Australia, which added only 24 m. during the five years. Yet the mileage open per 10,000 inhabitants in Australia, as a whole, far surpasses that in any of the other great geographical divisions.

Table VI. shows how nearly the same amount of railway mileage. In Mexico the national government is carrying out a consistent policy of developing its railway lines. It has succeeded in restoring the credit of these enterprises, and is proceeding with care and skill to form the lines into a national transportation system. In Argentina about half of the railways are owned and operated by the government, the balance being in the hands of private companies, largely controlled in England. Total: 113,581 miles; 254,192 single-track miles; total paid-up capital of £2,703,036.

Table IX shows the differences between various countries.

The railway operation through statistics has two distinct aspects. It has been well said that statistics furnish the means by which the railway manager disciplines his property; this is the aspect of control. On the other hand, the banker, the government official and the economist use railway statistics to obtain information which may be characterized as static rather than dynamic. Both uses ultimately rest upon comparison of the observed data from a certain property with the observed data from other properties, or with predetermined standards of performance.

In general, the British working unit supplied as public information has always been the goods-train-mile and the passenger-train-mile, these figures being the products of the number of trains into the number of miles they have travelled. In America, the basic units have been the ton-mile and the passenger-mile, and these figures are now required to be furnished to the Interstate Commerce Commission and to most of the state commissions as well. Both the British manager and the American manager, however, are supplied with a considerable number of daily, weekly and monthly reports, varying on different railways, which are not made public. The daily sheets usually include a summarized statement of the performance of every train on the line, covering all the amount of work done, the destination of the loads, &c. For a number of years there has been a movement in Great Britain to require the inclusion of ton-mile statistics in the stated returns to the Board of Trade, but most railway managers have objected to the change on the ground that their own confidential information was already adequate for purposes of control, and that ton-mile statistics would require additional clerical force to a costly extent. The Departmental Committee of the Board of Trade, sitting in 1909 to consider railway accounting forms, while recommending ton-miles to the careful consideration of those responsible for railway working in Great Britain, has deferred the question of their necessity in British practice to be still open, and held that, at all events, they should not be introduced under compulsion.

ECONOMICS AND LEGISLATION

It was at one time an axiom of law and of political economy that prices should be determined by free competition. But in the development of the railway business it soon became evident
RAILWAYS

that no such dependence on free competition was possible, either in practice or in theory. This difficulty is not peculiar to railways; but it was in the history of railway economy and railway control that certain characteristics which are now manifesting themselves in all directions where large investments of fixed capital are involved were first brought prominently to public notice.

For a large number of those who use a railway, competition in its more obvious forms does not and cannot exist. Independent carriers cannot run trains over the same line and underbid one another in offering transportation services. It would be practically impossible for a line thus used by different carriers to be operated either with safety, or with economy, or with the advantage to the public which a centralized management affords. It is equally impossible for the majority of shippers to enjoy the competition of parallel lines. Such duplication of railways involves a waste of capital. If parallel lines compete at all points, they cause ruin to the investors. If they compete at some points and not at others, they produce a discrimination or preference with regard to rates and facilities, which builds up the competitive points at the expense of the non-competitive ones. Such partial competition, with the discrimination it involves, is liable to be worse for the public than no competition at all. It increases the tendency, already too strong, towards concentration of industrial life in large towns. It produces an uncertainty with regard to rates which prevents stability of prices, and is apt to promote the interests of the unscrupulous speculator at the expense of those whose business methods are more conservative. So marked are these evils that such partial competition is avoided by agreements between the competing lines with regard to rates, and by divisions of traffic, or pools, which shall take away the temptation to violate such rate agreements. The common law has been somewhat unfavourable to the enforcement of such agreements, and statutes in the United States, both local and national, have attempted to prohibit them; but the public advantage from their existence has been so great as to render their legal disabilities imperceptible. In those parts of the continent of Europe where railways are owned and administered by state authority, the necessity for such agreements is frankly admitted.

But if rates are to be fixed by agreement, and not by competition, what principle can be recognized as a legitimate basis of railway rate-making? The first efforts at railway legislation were governed by the equal mileage principle; that is, the attempt was made to make rates proportionate to the distance. It was, however, soon seen that this was inadmissible. So much of the expense of the handling, both of freight and of passengers, was independent of the length of the journey that a mileage rate sufficiently large for short distances was unnecessarily burdensome for long ones, and was bound to destroy long-distance traffic, if the theory were consistently applied. The system has been retained in large measure in passenger business, but only because of the conflict which inevitably occurs between the authorities and the passengers with regard to the arrangement of breaking and resuming a journey when passenger rates are arranged on any other plan. In freight schedules it has been completely abandoned.

A somewhat better theory of rate regulation was then framed, which divided railway expenditures into movement expense, connected with the line in general, and terminal expense, which connected itself with the stations and station service. Under this system each consignment of freight is compelled to pay its share of the terminal expense, independently of distance, plus a mileage charge proportionate to the length of the journey or haul. There has been also a further attempt in England to divide terminal charges into station and service terminals, according to the nature of the work for which compensation is sought. But none of these classifications of expense reaches the root of the matter. A system of charges which compels each piece of traffic to pay its share of the charges for track and for stations overlooks the fundamental fact that a very large part of the expenses of a railway—more than half—is not connected either with the cost of moving traffic or of handling traffic at stations, but with the cost of maintaining the property as a whole. Of this character are the expenditures necessary for maintenance of way, for general administration and for interest on capital borrowed, which are almost independent of the total amount of business done, and quite independent of any individual piece of business. To say that all traffic must bear its share of these interest and maintenance charges is to impose upon the railways a rate which would cut off much of the long-distance traffic, and much of the traffic in cheap articles, which is of great value to the public, and which, from its very magnitude, is a thing that railways could not afford to lose. It is also a fact that with each recurring decade these general expenses (also called indirect, undistributed or fixed charges) have an increased importance as compared with the particular (direct, distributed or operating) expense attaching naturally to the particular portions of the traffic. For with increased density of population it becomes profitable to make improvements on the original location, even though this may involve increased charges for interest and for some parts of its maintenance, for the sake of securing that economy of operation, through larger train-loads, which such an improved location makes possible.

Whatever the ostensible form of a railway tariff, the contribution of the different shipments of freight to these general expenses is determined on the principle of charging what the traffic will bear. Under this principle, rates are reduced where the increase of business which follows such reduction makes the change a profitable one. They are kept relatively high in those cases where the expansion of business which follows a reduction is small, and where such a change is therefore unprofitable. This theory of charging what the traffic will bear is an unpopular one, because it has been misapplied by railway managers and made an excuse for charging what the traffic will not bear. Rightly applied, however, it is the only sound economic principle. It means taxation according to ability—that ability being determined by actual experiment.

In the practical carrying out of this principle, railways divide all articles of freight into classes, the highest of which are charged two or three, or even four times the rates of the lowest. This classification is based partly upon special conditions of service, which make some articles more economical to carry than others (with particular reference to the question whether the goods are offered to the companies in car-loads or in small parcels), but chiefly with regard to the commercial value of the article, and its consequent ability to bear a high charge or a low one. For each of these classes a rate-sheet gives the actual rate charge per unit of weight between the various stations covered by the tariff. This rate increases as the distance increases, but not in equal proportion; while the rates from large trade centres to other trade centres at a great distance are not higher than those to intermediate points somewhat less remote; if the law permits, there is a tendency to make them actually a little lower. Besides the system of charges thus prescribed in the classification and rate-sheet, each tariff provides for a certain number of special rates or charges made for particular lines of trade in certain localities, independently of their relation to the general system. If these special rates are published in the tariff, and are offered to all persons alike, provided they can fulfil the conditions imposed by the company, they are known as commodity rates, and are apparently a necessity in any scheme of railway charges. If, however, they are not published, and are given to certain persons as individual favours, they become a prolific source of abuse, and are quite indefensible from the standpoint of political economy.

While the superficial appearance of the railway tariff is different for different countries, and sometimes for different parts of the same country, the general principles laid down are followed in rate-making by all well-managed lines, whether state or private. It is a mistake to suppose that the question of public or private ownership will make any considerable difference in the system of rate-making adopted by a good railway. A state system will be compelled, by the exigencies
RAILWAYS

of the public treasury, to arrange its rates to pay interest on its securities; a private company will generally be prevented, by the indirect competition of railways in other parts of the country which it serves, from doing very much more than this. The relative merit of the two systems depends upon the question how we can secure the best efficiency and equity in the application of the principles thus far laid down. There are three different systems of control:

1. Private operation, subject only to judicial regulation, was exemplified most fully in the early railway history of the United States. Until 1870 railway companies were almost free from special acts of control; and, in general, any company that could raise or borrow the capital was allowed to build a railway wherever it saw fit. In the United Kingdom there was almost as much immunity from legislative interference with charges, but the companies were compelled to secure special charters, and to conform to regulations made by the Board of Trade in the interests of public safety. The advantage of this relatively free system of railway building and management is that it secures efficient and progressive methods. Most of the improvements in operation and in traffic management have had their origin in one of these two countries. The disadvantage attendant upon this system is that the courts are reluctant to exercise the right of regulation, except on old and traditional lines, and that in the face of new business methods the public may be inadequately protected. There is also this further disadvantage, that in the gradual progress of consolidation railway companies take upon themselves the aspect of large monopolies, of whose apparently unrestricted power the public is jealous. As a result of these difficulties there has been, both in the United Kingdom and in the United States, a progressive increase of legislative interference with railways. In the former the Railway and Canal Traffic Act of 1854 specially prohibited preferences, either in facilities or in rates. The Regulation of Railways Act of 1873 provided for a Railway Commission, which should be so constituted as to take cognizance of cases on the investigation of which the courts were reluctant to enter. Finally, the legislation of 1888 put into the hands of a reorganized Railway Commission and of the Board of Trade powers none the less important in principle because their action has been less in its practical effect than the advocates of active control demanded. In the United States the years from 1870 to 1875 witnessed sweeping and generally ill-considered legislation ("Granger Acts") concerning railway charges throughout the Mississippi valley; while the years from 1884 to 1887 were marked by more conservative acts, which culminated in the Interstate Commerce Act, prohibiting personal discrimination and gradually restricting discrimination between places, and providing for a National Commission of very considerable power—not to speak of the pooling clause, which was extraneous to the general purpose of the act, and has tended to defeat rather than strengthen its operation.

2. Operation by private companies, under specific provisions of the government authorities with regard to the method of its exercise, has been the policy consistently carried out in France, and less systematically and consistently in other countries under the domination of the Latin race. It was believed by its advocates that this system of prescribing the conditions of construction and operation of lines could promote public safety, prevent waste of capital and secure passengers and shippers against extortionate rates. These expectations have been only partially fulfilled. Well trained as was the civil service of France, the effect of this supervision in deadening activity was sometimes more marked than in its effect in preventing abuse. Moreover, such a system of regulation almost necessarily carries with it a guarantee of monopoly to the various companies concerned, and not infrequently large gifts in the form of subsidies, for without such aid private capital will not submit to the special burdens involved. These rights, whether of monopoly or of subsidy, form a means of abuse in many directions. Where the government is bad, they are a fruitful source of corruption; even where it is good, they enable the companies to drive hard bargains with the public, and prevent the expected benefits of official control from being realized.

3. State operation and ownership is a system which originated in Belgium at the beginning of railway enterprise, and has been consistently carried out by the Scandinavian countries and by Hungary. Since 1860 it has been the policy of Australia. It has generally come to be that of Germany and, so far as the finances of the countries allow, of Austria and Russia; British India also affords not a few examples of the same method. The theory of state ownership is excellent. So large a part of the railway charge is of the nature of a tax, that there seem to be a priori reasons for leaving the taxing powers in the hands of the agents of the government. In practice its operation is far more uncertain. Whether the intelligence and efficiency of the officials charged by the state with the handling of its railway system will be sufficient to make them act in the interest of the public as fully as do the managers of private corporations, is a question whose answer can only be determined by actual experience in each case. If they fail to have these qualities, the complete monopoly which a government enjoys, and the powers of borrowing which are furnished by the use of the public credit, increase instead of diminishing the danger of arbitrary action, unprogressiveness and waste of capital. Even in matters like public safety it is by no means certain that government authorities will do so well as private ones. The question is one which practical railway men have long since ceased to argue on general principles; they recognize that the answer depends upon the respective degree of talent and integrity which characterize the business community on the one hand and the government officials on the other.

Authorities.—On economics of construction and of operation, see Wellington, The Economic Theory of Railway Location (5th ed., New York, 1896). On principles governing railway rates in general, see Henry, The Railway Rates of the United States (London, 1877); British Railway Traders (London, 1891). On comparative railway legislation and the principles governing it, see Hadley, Railroad Transportation; its History and its Laws (New York, 1885). On the history of railway legislation in England, see Cohn, Untersuchungen über die örtliche Eisenbahnpolitik (Leipzig, 1874–83). On practice concerning rates in continental Europe, see Ulrich, Das Eisenbahnsteuerrecht (Berlin, 1886). (Since this was published, continental passenger rates have fallen. The French translation—Paris, 1898—gives Russian tariffs.) On the question of "nationalization" (i.e. state ownership and operation), see an article by Edgar Camden in the Quarterly Review (London) for October 1909, which cites, among other works on the subject, Chisholm's The Economics of Railway Nationalization (1908); Edwin A. Pratt's Railway Nationalization (1908); and E. A. Davis's Nationalization of Railways (1908).

BRITISH RAILWAY LEGISLATION

The first thing a railway company in Great Britain has to do is to obtain a special or private act of parliament authorizing the construction of the line. Not that the mere laying or working of a railway requires parliamentary sanction, but that the work does not interfere with other people's rights and interests. An example of a railway built without any legislative authority is the little mountain railway from Llanberis to the summit of Snowdon, which was made by the owner of the land through which it passes. Such a railway has no statutory rights and no special obligations, and the owner of it is liable to be sued for creating a nuisance if the working of the line interferes with the comfort of those residing in the neighbourhood. When, however, a company desires to construct a line on a commercial scale, to acquire land compulsorily, to divert rivers and streams, to cross roads either on the level or by means of bridges, to pass near houses, to build tunnels or viaducts, and to execute all the other works incidental to a railway, and to work the line when completed without interference, it is essential that the authority of parliament should be obtained. The company therefore promotes a bill, which is considered first by select committees of the two houses of parliament, and afterwards by the two houses themselves, during which period it faces the opposition, if any, of rival concerns, of local authorities and of hostile landowners. If this is successfully overcome, and the proposals meet with the
approval of parliament, the bill is passed and, after securing the Royal Assent, becomes an act of parliament. The company is then free to proceed with the work of construction, and at once becomes subject to various general acts, such as the Companies Clauses Act, which affects all joint-stock companies incorporated by any special act; the Land Clauses Act, which has reference to all companies having powers to acquire land compulsorily; the Railway Clauses Act, which imposes certain conditions on all railways alike (except light railways); the various Regulation of Railways Acts; the Carriers Protection Act; acts for the conveyance of mails, parcels, troops; acts relating to telegraphs, to the conveyance of workmen and to the housing of the labouring classes; and several others which it is unnecessary to specify. From the early days of railways parliament has also been careful to provide for the safety of the public by inserting in the general or special acts definite conditions, and by laying upon the Board of Trade the duty of protecting the public in respect of any railway.

The first act which has reference to the safety of passengers is the Regulation of Railways Act of 1842, which obliges every railway company to give notice to the Board of Trade of its intention to open the railway for passenger traffic, and places upon that public department the duty of inspecting the line before the opening of it takes place.

If the officer appointed by the Board of Trade should, after inspection of the railway, report to the department that in his opinion "the opening of the same would be attended with danger to the public using the same, by reason of the incompleteness of the works or permanent way, or the insufficiency of the establishment for working such railway," it is lawful for the department to direct the company to postpone the opening of the line for any period not exceeding one month at a time, the process being repeated from month to month as often as may be necessary. The company is liable to a fine of twenty pounds a day if it should open the line in contravention of such order or direction. The inspections made by the officers of the Board of Trade under this act are very complete: the permanent way, bridges, viaducts, tunnels and other works are carefully examined; all iron or steel girders are tested; stations, including platforms, stairways, waiting-rooms, &c., are inspected; and the signalling and "interlocking" are thoroughly overhauled.

A code of requirements in regard to the opening of new railways has been drawn up by the department for the guidance of railway companies, and as the special circumstances of each line are considered on their merits, it rarely happens that the department finds it necessary to prohibit the opening of a new railway. The Regulation of Railways Act of 1871 extends the provisions of the above act to the opening of any additional line of railway, and to the "block" system of working, and also requires the insertion of certain local railways that are subsequently included in a Blue-book and presented to parliament. It should be noted that although the inspecting officer may in his report make any recommendations that he may think fit with a view to guarding against any similar accident occurring in the future, no power is given to the Board of Trade, or to any other authority, to compel any railway company to adopt such recommendations. This omission is sometimes held to be an error, but as a fact it is an advantage. The moral effect of the report, with the criticisms of the company's methods and recommendations appended thereto, is great, and it rarely happens that a company refuses to adopt, or at any rate to test, the recommendations so made. If, on the other hand, the company is of opinion that the suggestions of the inspecting officer are not likely to prove beneficial, or are for any reason unadvisable, it is at liberty to reject them, the responsibility of doing so resting entirely upon itself. The effect of this latitude is to give the company ample discretion in the matter, and to enable the act to be administered in such a way as to prevent undue interference.

In 1878 a very important act was passed placing upon the Board of Trade the obligation to call upon railway companies throughout the United Kingdom (1) to adopt upon all passenger lines the "block" system of working; (2) to "interlock" their points and signals; (3) to fit all trains carrying passengers with some form of automatic continuous brake. Prior to this some companies had, to a certain extent, done these things, but few, if any, were completely equipped in these respects. A reasonable period was afforded them, according to circumstances, to comply with these requirements, and at the present time the work is practically complete. In this respect the lines of the United Kingdom are far ahead of those of any other country, and a diminution of accidents, particularly of collisions, has resulted therefrom. America is now following the lead thus set, and all the principal lines in the United States have adopted block working and interlocking, but a great deal still remains to be done. In certain respects, on the other hand, America has gone further than the United Kingdom, especially in the matter of automatic signalling, and in the operating of points and signals by electrical power or air-pressure instead of manual labour. In America, also, freight trains are fitted with an automatic continuous brake, whereas in the United Kingdom this appliance is required by law only in the case of passenger trains, and in fact is not fitted to goods and mineral trains except in a few isolated instances.

The above-named acts enable the Board of Trade to take all the necessary steps to ensure that the safety of passenger trains is sufficiently guarded. More recently legislation has been passed to safeguard the lives and interests of railway servants. In 1893 an act was passed giving the Board power to interfere if or when representations are made to them by or on behalf of any servant or class of servants of a railway company that the hours of work are unduly long, or do not provide sufficient intervals of uninterrupted rest between the periods of duty, or sufficient relief in respect of Sunday duty. In such cases the company concerned may, after inquiry, be called upon to submit such a
RAILWAYS

schedule of the hours during which the man or men are employed as will bring those hours within limits which appear to the department reasonable. In the event of the company failing to comply with the demands of the department, the latter is empowered to refer the case to the Railway and Canal Commissioners, who form a special Court constituted by the Railway and Canal Traffic Act of 1888, for deciding, among other things, questions relating to rates and charges, for protecting traders from undue charges and undue preference, for regulating questions of traffic, and for deciding certain disputes between railway companies and the public. The Commissioners are then empowered to deal with the matter, and if "a railway company fail to comply with any order made by the Railway and Canal Commissioners, or to enforce the provisions of any schedule" approved by them, it is liable to a fine of a hundred pounds for every day during which the default continues. This act has been the means of effecting a considerable reduction in the hours worked by railway men on certain railways, and no case has yet arisen in which a reference to the Commissioners has been necessary. Such modifications of the hours of work have not only been beneficial to the men, but have improved the discipline of the staff and the punctuality and regularity of the train service, particularly in respect of the goods trains.

The Notice of Accidents Act of 1884, which obliges employers of labour to report to the Board of Trade, when "there occurs in any employment" as defined by the schedule of the act, "any accident which causes to any person employed therein, either loss of life or such bodily injury as to prevent him on any one of the three working days next after the occurrence of the accident from being employed for five hours on his ordinary work," affects railways in course of construction, but not, as a rule, otherwise.

Although the administration of the above-mentioned acts of parliament has had a beneficial effect upon the safety of the public, and has enabled an enormous volume of traffic to be handled with celerity, punctuality and absence of risk, it has during recent years come to notice that the number of casualties among railway servants is still unduly great, and in 1890 a Royal Commission was appointed to investigate the causes of the numerous accidents, fatal and non-fatal, to railway men. As a consequence of the report of this Commission the Railway Employment (Prevention of Accidents) Act of 1900 was passed, putting upon the Board of Trade the duty of making "such rules as they think fit with respect to any of the subjects mentioned in the schedule to this act, with the object of reducing or removing the dangers and risks incidental to railway service." Rules may also be made in respect to other matters besides those mentioned in the schedule, and companies may be called upon to adopt or reject, as the case may be, any appliance, the use or disuse of which may be considered desirable in the interest of the men. Before, however, the rules so made become binding upon the companies, the latter have the right of appealing against them to the Railway Commission. Failure to comply with any of the rules renders a company "liable for each offence, on conviction under the Summary Jurisdiction Acts, to a fine not exceeding fifty pounds, or in the case of a continuing offence to a fine not exceeding ten pounds for every day during which the offence continues after conviction." Rules drafted by the Board of Trade under this act came into force on the 8th of August 1902, the subjects referred to being (1) labelling of wagons; (2) movements of wagons by propping and tow-roping; (3) power-brakes on engines; (4) lighting of stations and sidings; (5) protection of points, rods, &c.; (6) construction and protection of gauge-glasses; (7) arrangement of tool-boxes, &c., on engines; (8) provision of brake-vans for trains upon running lines beyond the limits of stations; (9) protection to permanent-way men when relaxing or repairing permanent way. The final settlement of a rule requiring brake-levers to be fitted on both sides of goods-wagons was, however, deferred, owing to objections raised by certain of the railway companies.

Other acts which are of importance in connexion with accidents are the Accidents Compensation Act of 1846, the Employers' Liability Act of 1880, and the Workmen's Compensation Act of 1897.

The public acts of parliament referring to British railways are collected in Bigg's General Railway Acts.

(H. A. V.)

AMERICAN RAILWAY LEGISLATION

Before 1870.—The earliest legislation is contained in charters granted by special act, for the construction of railways. These special acts gradually gave way to general statutes under which railway corporations could be created without application to the legislature. In the east, where, as a rule, charters had been uniform and consistent, the change to general incorporation law was due to a desire to render incorporations speedier and less expensive. In the west, general laws came rather as a result of the abuses of special legislation. By 1850, general incorporation laws were found in nearly all the eastern states, and by 1870 in those of the west.

Early legislation was confined almost entirely to matters of construction. In cases where statutes did touch the question of regulation, they had to do with the operation of trains and with the provision of facilities for shippers and passengers, rather than with questions of rates. It was natural that this should be so, for the new transportation agency was so much more efficient than anything previously available that the people were eager to take advantage of its superior service. As a rule, the making of rates was left to the corporations. If the maximum rates were prescribed, as they sometimes were, the limit was placed so high as to be of no practical value for control. Such crude attempts as were made to prevent rates from being excessive concerned themselves with profits, and were designed to confiscate for the state treasury any earnings beyond a certain prescribed dividend. Publicity of rates was not generally required, and provisions against discrimination were rare. In the period before 1850 there was but little realization of the public nature of the railway industry and of the responsibilities of injury to the public if railway corporations were left uncontrolled.

In regions where capital was lacking eagerness for railway facilities led the people to demand the direct co-operation of the state, and many projects, most of which ended in disaster, were undertaken either by the state itself or through the aid of the state's credit. For example, Michigan, in 1837, in the first session of its state legislature, made plans for the construction of 557 miles of railway under the direct control of the state, and the governor was authorized to issue bonds for the purpose. The unfortunate results of this policy led many of the states, from about 1850, to put constitutional limitations upon the power of their legislatures to lend the state's credit or to involve the state as stockholder in the affairs of any corporation.

As railway building increased in response to traffic needs, and as the consolidation of short lines into continuous systems became applicable to railways became somewhat broader in scope and more intelligent. About 1850 there began to appear on the statute books laws requiring publicity of rates and the submission of annual reports to the legislature, prescribing limits to corporate indebtedness, and also making provision for safety in operation and for the character and quality of railway service. Consolidation and leasing were commonly permitted in the case of continuous lines, but were regularly prohibited in the case of parallel and competing lines. The practice of pooling seems not to have attracted the attention of the legislature. In general it may be asserted that legislation of this period was ill-considered, haphazard, and on a petty scale. Moreover, it was of little practical importance even within its narrow range, for it does not appear to have been generally enforced.

1870-1900.—Railway legislation first assumed importance in connection with the "Granger Movement" in the middle west. There the policy of subsidies for railway building had been carried to a reckless extreme. Roads had been constructed in advance of settlement, and land-seekers had been
transported to these frontier sections only to become dependent upon the railways for their very existence. To the unusual temptation thus afforded to favouritism and discriminations in rates, the railways generally yielded. This preferential and discriminating policy, combined with other causes which cannot here be discussed, resulted in the Granger legislation of the 'seventies. In the first instance laws were enacted prescribing schedules of maximum freight and passenger rates with stringent penalties against rebates and discriminations. These measures proving unsatisfactory, they were soon superseded by statutes creating railway commissions with powers of regulation. The commission method of control was not a new one. Such bodies, established to appraise land for railway purposes, to apportion receipts and expenditures of interstate traffic, and in a general way to supervise railway transportation, had been in existence in New England before 1860, one of the earliest being that of Rhode Island in 1839. In 1869 Massachusetts had instituted a commission of more modern type, which was given only powers of investigation and recommendation, the force of public opinion being relied upon to make its orders effective. Western commissions, the offspring of the Granger movement, were of a more vigorous type. Most of them had power to impose schedules of maximum rates; practically all of them had authority to prescribe rates upon complaint of shippers; and they could all seek the aid of the courts to enforce their decrees. Their power to initiate rates, conferred upon them by their legislatures, was sustained by the Supreme Court of the United States, the Court reserving to itself only the power to decide whether the prescribed rates were reasonable.

But the jurisdiction of the state commissions was, by judicial interpretation, limited to commerce beginning and ending within the limits of the single state. The most important part of railway transportation, that which was interstate in character, was left untouched. It was this impotence of the state commission that furnished the strongest incentive to Congressional action. The result was the passage, in 1887, of the Interstate Commerce Act, which was directed towards the extirpation of illegal and unjust practices in commerce among the states. Its primary purpose was to embody in statutory form the common-law principle of equal treatment under like circumstances, and to provide machinery for enforcement. It aimed at the prohibition of discrimination between persons, places and commodities. It made provision for publicity of rates and for due notice of any change in rates; it forbade pooling of freight or earnings, and required annual reports from the carriers. For its enforcement, it created an Interstate Commerce Commission of five members, with powers of investigation, and with authority to issue remedial orders upon complaint and after hearing. Findings of the Commission were to be prima facie evidence in any court proceeding for the enforcement of its orders.

In this connexion, reference should be made to the Anti-Trust Act of 1890, which, by its judicial interpretation, has been held to invalidate free lines and to forbid rate agreements between competing carriers.

The act of 1887 remained in force without substantial amendment until 1906, although with constantly diminishing prestige, a result largely due to adverse decisions concerning the powers of the Commission. Ten years after the passage of the law, the court decided that the Commission had no power to prescribe a rate, and that its jurisdiction over rates was confined to a determination of the question whether the rate complained of was unreasonable. The Commission had much difficulty at the beginning in securing the testimony of witnesses, who invoked the Constitution of the United States as a bar against self-incrimination, and the immunity clause of the act had to be amended before testimony could be obtained. The so-called "long-and-short-haul clause," which forbade a greater charge for a long than for a short haul over the same line, if circumstances were substantially similar, was also robbed of all its vitality by court decision. The section requiring annual reports, while it led to the creation of a Bureau of Statistics, did not give the Commission power to compel complete or satisfactory answers to its requests for information. The only element of real strength that the statute acquired during the first twenty years of its history came from the Elkins Act of 1903, which stipulated that the published rate should be the legal rate, and declared any departure from the published rate to be a misdemeanour. It held shipper as well as carrier, and corporation as well as its officer or agent, liable for violations of the act, and conferred upon United States courts power to employ equity processes in putting an end to discrimination. Conviction for granting rebates was by this law made easier and more effective.

Since 1900.—The movement in favour of more vigorous railway regulation became pronounced after 1900. Twenty years of experience and observation had revealed the defects of the earlier legislation, and had concentrated public attention more intelligently than ever before upon the problem of strengthening the weak spots. The state commissions, since their establishment in the 'seventies and the 'eighties, had increased their functions and influence. Many of them, beginning only with powers of recommendation, had obtained a large extension of authority. By 1908, thirty-five of the forty state commissions were of the mandatory type, and thirteen of these had been created since 1904. They had been given power to require complete annual reports from carriers, with a consequent great increase in public knowledge concerning railway operation and practice. The most recent type of state commission is the so-called Public Utility Commission, of which the best examples are those of New York and Wisconsin, established in 1907. In both states, the Commissions have power over electric railways and local public utilities furnishing heat, light and power, as well as over steam railway transportation, and the Wisconsin Commission also has control over telephone companies. In both states the consent of the Commission is necessary for the issue of corporate securities.

Mention should be made of the mass of general legislation passed, principally by western states, since 1905, in response to a popular demand for an enforcement of the laws relating to transportation rates. This demand has led many instances led to ill-considered legislation, has frequently ignored the prerogatives and even the existence of the state commissions, and has brought about the passage by state legislatures of maximum freight and passenger rate laws, with rates so low in many cases that they have been set aside by the courts as unconstitutional. The numerous laws limiting the fare for passengers to two cents per mile are an illustration of this tendency.

In the field of federal legislation, no significant change took place until the passage of the Hepburn Act of 1906, which was an amendment of the act of 1887. While failing to correct all the defects in the original statute, the amended law was a decided step in the direction of efficient regulation. It increased the jurisdiction of the Commission by placing under the act express companies, sleeping-car companies and pipe lines for the transportation of oil. It extended the meaning of the term "railroad" to include switches, spurs and terminal facilities, and of the term "transportation" to include private cars, all collateral services, such as refrigeration, elevation and storage. The Elkins Act of 1903 was incorporated in the statute, and an imprisonment penalty was added to the existing fine. It forbade the granting of passes except to certain specified classes,—a provision entirely absent from the original measure. It expressly conferred upon the Commission the power to prescribe maximum rates, upon complaint and after hearing, as well as to make joint rates, and to establish through rates when the carriers had themselves refused to do so. It enacted that published rates should not be changed except on thirty days' notice, whether the change involved an increase or a decrease, and it required annual reports to be made under oath, penalties being prescribed for failure to comply with the Commission's requests for information. Power was also given to prescribe uniform systems of accounts for all classes of carriers, and to employ special examiners to inspect the books and accounts.

Carriers were forbidden to keep any accounts, records or memoranda other than those approved by the Commission.
Orders of the Commission became effective within such time, not less than thirty days, as the Commission should prescribe, and penalties began to take effect from the date fixed by the Commission, unless the carrier secured an injunction from the Court suspending the order. Such injunction might not issue except after hearing, of which five days' notice must be given. Decisions of the Commission were not reviewable by the Court unless the Commission had exceeded its authority, or had issued an unconstitutional order.

A new and important act was signed by the President on the 18th of June 1910. It created a Commerce Court (composed of five judges nominated by the president of the United States from the Federal circuit judges), transferred to it jurisdiction in cases instituted to enforce or set aside orders of the Inter-State Commerce Commission, and made the United States instead of the Commission a party in all such actions. The law forbids a railway or any other common carrier to charge more for a short haul than for a long haul over the same line, unless, in special cases, it is authorized to do so by the Commission. It forbids a railway which has reduced its rates while in competition with a water route to raise them again when the competition has ceased, unless the Commission permits it to do so because of other changed conditions. It extends the initiative of the Commission from the investigation of complaints to the investigation of rates on its own motion; authorizes it to suspend rates in advance of their going into effect, pending an investigation which may be continued for ten months, and to establish through routes; and provides for a special commission, appointed by the President, to investigate questions pertaining to the issuance of railway securities.

ACCIDENT STATISTICS

Statistics of railway accidents may be divided into three classes: casualties (a) to passengers, (b) to servants or employees and (c) to other persons; and again into (1) train accidents, (2) accidents to persons doing work on or about trains and (3) other accidents.

Such statistics are studied mainly with the object of learning the lessons which they may afford as to preventive measures for the future; and from this point of view the most important element is the single item of passengers killed in train accidents (a 1). The number injured is, indeed, a fact of interest, no less than the number killed, but comparisons under this head are unsatisfactory because it is impracticable or unprofitable to go into sufficient detail to determine the relative seriousness of injuries except in certain cases. The statistics of casualties in general, however, are a necessary stimulus to improvement. Accidents to passengers other than those caused by collisions or derailments of trains are very largely due to causes which it is fair to class either as unavoidable or as due mainly to the fault or carelessness of the victim himself. That this is so is indicated by the fact that, although the railways—always made to suffer severely in pecuniary damages for injuries for which their officers or servants are held responsible by the courts—have for years taken almost every conceivable precaution, the number of accidents, in proportion to the number of persons travelling, diminishes but slowly.—so slowly that, in view of the variety of conditions to be considered, it would hardly be safe to conclude that the diminution is due to any definite improvement in the safeguards provided. Collisions, on the other hand, are preventable, and derailments nearly so, and the records of deaths and injuries in this class in successive years are therefore justly taken as an index to the efficiency with which the railways are managed.

The number of servants killed in train accidents is the next in importance. The safety of passengers is, indeed, the first care of the railway manager; but the employees, exposed to many risks from which the passengers are protected, must be looked after. On the British railways the men who run the trains are safeguarded very efficiently, and the collisions and derailments which are serious enough to do injury to the trainmen or the enginemen are really rare. The roadway, tracks and rolling stock are so well maintained that those causes which lead to the worst derailments have been eliminated almost completely, and the record of serious collisions has been reduced nearly to zero by the universal use of the block system and by systematic precautions at junctions. In America the record is far less satisfactory. The best railways of the United States and Canada have, indeed, been greatly improved, and their main lines approach the high standards of safety which prevail in Great Britain, both as regards maintenance and care of roadway and vehicles (as a preventive of derailments) and the use of the block system (as a preventive of collisions); but when the inquirer looks at America as a whole—the total length of its railroads is running over 30,000 mi., and the total of the United Kingdom—he is considering a figure which includes an enormous mileage of railway lying in thinly settled regions where the high standards of safety maintained on the best railways have scarcely been thought of. The duty of a railway with deficient plant or facilities would seem to be to make up for their absence by moderating the speeds of its trains, but public sentiment in America appears so far to have approved, at least tacitly, the combination of imperfect railways and high speeds.

Apart from collisions and derailments, a large proportion of all accidents is found to be due primarily to want of care on the part of the victims. Accidents to workmen in marshalling, shunting, distributing and running trains, engines and cars, may be taken as the most important class, after train accidents, because this work is necessary and important and yet involves considerable hazard. On British railways the duty of the companies to provide all practicable safeguards and to educate and caution the servants may be said to have been faithfully performed, and the accident totals must be taken as being somewhat near the "irreducible minimum"—unless some of the infirmities of the human mind can be cured. In America the number of men killed and injured in handling freight trains has been very large. In the year ending June 30, 1909, exclusive of casualties due to collisions, derailments and other accidents to trains, the number killed was 811 and of injured 28,156 (Accident Bulletin, No. 32, p. 14). The number killed (811) is equal to about three in every thousand trainmen employed. From this and all other causes, the number of trainmen killed in the year ending June 30, 1909, was about 8 in 1000.

The use of automatic couplers for freight cars throughout the United States, introduced in 1863–1900, greatly reduced the number of deaths and injuries in coupling, and the use of air brakes on freight cars, now universal, has reduced the risk to the men by making it less necessary for them to ride on the roofs of high box-cars, while at the same time it has made it possible to run long trains with fewer men; but except in features the freight service continues to be a dangerous occupation. The high and heavy cars, the high speeds, the severe weather in the northern states in winter, the fluctuating nature of the business, resulting often in the employment of poorly qualified men and in other irregularities, are among the causes of this state of things.

Being struck or run over by a train while standing or walking on the track is the largest single cause of "railway accidents." Workmen are killed and injured in this way, both while on duty and when going to and from their work; passengers, with or without right, go in front of trains at stations and at highway crossings at grade level; and trespassers are killed and injured in large numbers on railways everywhere, at and near stations, at crossings, and out on the open road, where they have no shadow of right. Of trespassers the number killed per mile of
ACCIDENT STATISTICS

RAILWAYS

line is about as large in England as in America, the density of population and of traffic in Great Britain apparently counter-balancing the laxity of the laws against trespassing in America. In the thickly settled parts of the United States the number of trespassers killed on the railway tracks, including vagrants who suffer in collisions and derailments while stealing rides, is very large. In New York and four adjacent states, having about as many miles of railway as the United Kingdom, the number in the year ending June 30, 1907, was 1,552. In the United Kingdom the number for the corresponding year was 447, or less than one-third.

As was suggested at the outset, railway accident statistics are useful only as showing how to make life and limb safer, though in pursuing this object increased economy also should be secured. Railways have always been held by the legislatures and by the courts strictly accountable for their shortcomings, so far as accountability can be enforced by compelling the payment of damages to victims of accidents; but in spite of this, a want of enterprise and even some apparent neglect of passengers' and servants' plain rights, have often been apparent, and the Board of Trade, with its powers of supervision, inspection and investigation, must therefore be classed as one of the most beneficent factors in the promotion of safety on British railways. Its powers have been exercised with the greatest caution, yet with consistent firmness; and the publicity which has been given to the true and detailed causes of scores and scores of railway accidents by the admirable reports of the Board of Trade inspectors has been a powerful lever in improving the railway service. Useful compulsory laws regarding the details of train management are difficult to frame and hard to carry out; but the Board has exercised a persistent persuasiveness and has secured most of its objects. Its investigations justified the law making the break in the system compulsorily, thus removing the worst danger of railway travel. Its constant and impartial expositions of cases of over-work and insufficient training of employees have greatly helped to elevate the character of these employees.

In the United States the governments have done far less. A majority of the states have railway commissions, but the investigation of railway accidents, with comparatively few exceptions, has not been done in such a way as to make the results useful in promoting improved practice. Many of the commissions have done little or nothing of value in this respect. The Federal government, having authority in railway matters only when interstate traffic is affected, gathers statistics and publishes them; but in the airing of causes—the field in which the British Board of Trade has been so useful—nothing so far has been done except to require written reports monthly from the railways. These are useful so far as they go, but they lack the impartiality that would be secured by an inquiry such as is held in England.

24. Miscellaneous | 1 | 1 |

Percentages.—On British railways the casualties from train accidents, especially fatal injuries, have been reduced to so small a proportion of the number of passengers travelling, or the number of servants employed, that the figures showing the percentages vary from year to year considerably; but in other classes of accidents, in which a large proportion of the cases may be classed as unpreventable, the percentages do not vary greatly. The following are the more significant ratios in the year 1909, as shown in the Board of Trade returns:

(a) Passengers killed in train accidents, approximately | 1 in 83,000,000 |
(b) Passengers injured in train accidents, approximately | 1 in 3,000,000 |
(c) Servants killed in train accidents | (1908, approximately 1 in 6,000,000) |
(d) Servants killed in work about trains, &c. (excluding train accidents), ratio killed to number employed | 1 in 250 |
(e) Goods guards and brakemen, ratio killed to number employed | 1 in 4,378 |
(f) Shunters, ratio killed to number employed | 1 in 400 |
(g) Engine drivers, ratio killed to number employed | 1 in 337 |
(h) Passenger guards, ratio killed to number employed | 1 in 618 |

Railway Accidents in America.—The statistics of accidents in America are kept in a form somewhat different from the foregoing. Table XIV. is taken from the Accident Bulletin of the Interstate Commerce Commission (No. 32), the items being numbered to correspond as nearly as practicable with the numbers in the British table (No. X.). The items 7–8 embrace the statistics which most nearly correspond to the items 7–12 in the British table.

</tbody>
</table>

Year ending June 30, 1909.

The salient feature of Table XIV. is the diminution from 1908 to 1909. This is mainly due to a great falling off in traffic, because of a general business depression; from 1907 to 1909 the reduction in the accident record is still greater. In items 1 and 2 the increase in safety is due in part, no doubt, to the extension of the use of the block system. The accidents to "other persons" cannot readily be compared with items 7–12 in the British record, except as to the total and a few of the items.

In any comparison between British and American records the first point to be borne in mind is the difference in mileage and traffic. The American railways aggregate approximately ten times the length of the British lines, but in train miles the difference is far less. In the latest years in which comparisons can be made, the passenger journeys in the United Kingdom amounted to 1,500 millions (including season-ticket holders, estimated) and the train miles to 42,815 million, while the corresponding figures in the United States were 873 million and 1,557 million. The average length
of the passenger's journey in the United States is reported to be about 32 m.; in Great Britain it is undoubtedly less, but no record is published. Of the total train mileage in America more than half is freight; in Great Britain much more than half is passenger.

</tbody>
</table>

Table XV shows the casualties on American railways in 1907 and 1908 (year ending June 30). These figures differ from those in Table XIV, because of differences in classification. In Table XIV, the item "passengers killed" includes those on some electric railways, which presumably are not covered in the statement here given; also passengers in freight trains, &c. Under "employees" this table includes men in shops, &c., not shown in Table XIV.

In 1907 one passenger in 2,318,051 was killed, and one in 1,004 was injured, in train accidents. The number of employees killed in train accidents was 12-9 in 10 million train miles. Of train men (including engine-drivers and firemen), one out of 125 employed was killed (all causes), and one in eight injured.

The great differences between the records of the United States and the United Kingdom seem to afford justification for the view, which has often been expressed, that in America the spirit of hurry and recklessness manifest in many of the activities of the people prevails even among the men on whom rests the grave responsibility of running trains in safety. Yet the best safety devices are made in America, and means of reducing these death records are well known.

**France.**—Railway accidents in France are recorded in a shape somewhat different from that found in either Great Britain or America. The principal items for the years 1906 and 1907 are shown in Table XVI. The length of railways in the republic was 39,063 km. (24,832 m.), the number of persons employed on them was rather less than 300,000, the number of passengers carried annually being between 10 and 11 million. The number of passengers (36) killed in train accidents in 1907 equaled to 0-759 per million passengers carried and 0-0024 per million kilometres travelled by passengers, or 0-1503 per million kilometres travelled by trains.

</table>

The most significant item in the table, 36 passengers killed in train accidents, is perhaps to be considered as abnormally large, the totals under this head for the preceding six years beginning with 1901 being 7, 35, 3, 18, 4, 14, or an average of 11-57 per year. The French secretary of Public Works, who has furnished these statistics, keeps also similar records of the local or light railways, on which the number of fatal accidents appears to be exceedingly small.

**Germany.**—The number of persons killed on the railways of the German Empire in the year 1907 was 1,249, classified as in Table XVII. This number does not include suicides and attempts at suicide, of which there were 333, all but 24 being successful. In these statistics, the third item, "other persons," includes post office and customs officials and other persons connected with the railway service, as well as railway officers and servants off duty. The totals of passengers killed and injured in train accidents are not separated from those killed and injured from other causes, but ratios are given showing that for four years no passengers were killed in this class.

**FINANCIAL ORGANIZATION**

The methods of financing railway enterprises, both new projects and existing lines, have been influenced very largely by the attitude of the state and of municipal authorities. Railways may be built for military reasons or for commercial reasons, or for a combination of the two. The Trans-Siberian railway was a military necessity if Russia was to exercise dominion throughout Siberia and maintain a port on the Yellow Sea or the Sea of Japan. The Union Pacific railroad was a military necessity to the United States if the authority of the national government was to be maintained in the Far West.

The cost of such ventures and the detailed methods by which they are financed are of relatively small importance, because they are not required to earn a money return on the investment. To a lesser degree, the same is true of railways built for a special instead of a general commercial interest. The Baltimore & Ohio railroad was built to protect and further the commercial interests of the city of Baltimore; the Cincinnati Southern railroad was built to connect the city of Cincinnati, which built the line in the seventies for commercial protection against Louisville, Ky. From a commercial point of view such ventures are differentiated from railway projects built for general commercial reasons because they do not depend on their own credit. The government, national or local, furnishes the borrowing power, and makes the best bargain it can with the men it designates to operate the line.

Where a railway is built for general commercial reasons, however, it must furnish its own credit; that is to say, it must convince investors that it can be worked profitably and give them an assured return on the funds they advance. The state is interested in the commercial railway venture as a matter of public policy, and because it can confer or withhold the right of eminent domain, without which the railway builder would be subjected to endless annoyance and expense. This governmental sanction has been obtained only with difficulty, and after the exercise of numerous legal forms, in Great Britain and on the continent of Europe. In the United States, on the other hand, it has been obtained with considerable ease. In the earlier years of American railway building, each project was commonly the subject of a special law; then special laws were in turn succeeded by general railway laws in the several states, and these in turn have come to be succeeded in most parts of the country by jurisdiction vested in the state railway commission. Each of these changes has tended to improve the existing status, to legitimize railway enterprise, and to safeguard capital or investment.

The laws regulating original outputs for capital were strictly drawn in Great Britain and on the continent of Europe; in America they were drawn very loosely. As a result it has been far easier for the American than for the European railway builder to take advantage of the speculative instinct in obtaining money. Instead of the borrowing power being restricted to a small percentage of the total capital, as in European countries, most of the railway mileage of America has been built with borrowed money, represented by bonds, while stock has been given freely as an inducement to subscribe to the bonds on the...
RAILWAYS

The growth of railways has been accompanied by a world-wide tendency toward consolidation, and ventures into large groups of lines able to aid one another in the exchange of traffic and to effect economies in administration and in the purchase of supplies. Both in England and in America this process of consolidation has been obstructed by all known legislative devices, because of the widespread belief that competition in the field of transportation was necessary if fair prices were to be charged for the service. But the general tendency to regulate rates by authority of the state has apparently rendered unnecessary the old plan of rate regulation through competition, even if it had not been demonstrated often and again that this form of regulation is costly for all concerned and is effective only during rare periods of direct conflict between companies. Nevertheless, in spite of difficulties, consolidation has gone on with great rapidity. When Mr. E. H. Harriman died he exercised direct authority over more than 50,000 m. of railway, and the tendency of all the great American railway systems, even when not tied to one another in common ownership, is to increase their mileage year by year by acquiring tributary lines. The smaller company exchanges its stock for stock of the larger system on an agreed basis, or sells it outright, and the bondholders of the absorbed line often have a similar opportunity to exchange their securities for obligations of the parent company, which are on a stronger basis or have a broader market. Similarly in Great Britain there is a tendency towards combination by mutual agreement among the companies while they still preserve their independent existence.

Table XVIII shows the paid-up capital, gross receipts, net receipts and proportion of net receipts to total paid-up capital on the railways of the United Kingdom for a series of years.

R. (Mo.)

CONSTRUCTION

Location.—An ideal line of railway connecting two terminal points would be perfectly level and perfectly straight, because in that case the resistance due to gradients and curves would be eliminated (see § Locomotive Power) and the cost of mechanical operation reduced to a minimum. But that ideal is rarely if ever attainable. In the first place the route of a railway must be governed by commercial considerations. Unless it be quite short, it can scarcely ever be planned simply to connect its two terminal points, without regard to the intervening country; in order to be of the greatest utility and to secure the greatest revenue it must be laid out with due consideration of the traffic
RAILWAYS

arising at intermediate places, and as these will not usually lie exactly on the direct line, deviations from straightness will be rendered necessary. In the second place, except in the unlikely event of all the places on the selected route lying at the same elevation, a line that is perfectly level is a physical impossibility; and from engineering considerations, even one with uniform gradients will be impracticable on the score of cost, unless the surface of the country is extraordinarily even. In these circumstances the constructor has two broad alternatives between which to choose. On the one hand he may make the line follow the natural inequalities of the ground as nearly as may be, avoiding the elevations and depressions by curves; or on the other he may aim at making it as nearly straight and level as possible by taking it through the elevations in cuttings or tunnels and across the depressions on embankments or bridges. He will incline to the first of these alternatives when cheapness of first cost is a desideratum, but, except in unusually favourable circumstances, the resulting line, being full of sharp curves and severe gradients, will be useless for fast running and will be unable to accommodate heavy traffic economically.

If, however, cost within reasonable limits is a secondary consideration and the intention is to build a line adapted for express trains and for the carriage of the largest volume of traffic with speed and economy, he will lean towards the second.

In practice every line is a compromise between these two extremes, arrived at by carefully balancing a large number of varying factors. Other things being equal, that route is best which will serve the district most conveniently and secure the highest revenue; and the most favourable combination of curves and gradients is that by which the annual cost of conveying the traffic which the line will be called on to carry, added to the annual interest on the capital expended in construction, will be made a minimum.

**Cuttings and Embankments.**—A cutting, or cut, is simply a trench made in the surface of the ground, and the surface below the bottom of the cut is formed into one or more layers of rails, and is covered with earth or other material in such a manner that the line may continue on its grade. The sides of the cut vary according to the nature of the ground, the amount of moisture present, &c. In solid rock they may be vertical; in gravel, sand or common earth they must, to prevent slipping, rise 1 ft. for 1½ or 2 ft. of base, or even more in treacherous clay. In soft material the excavation may be performed by mechanical excavators or "steam navvies," while in hard clay it may be necessary to resort to blasting. Except in hard rock, the top width of a cutting, and therefore the amount of material to be excavated, increases rapidly with the depth; hence if a cutting exceeds a certain depth, which varies with the particular circumstances, it may be more economical, instead of forming the sides at the slope at which the material of which they are composed will stand, to make them nearly vertical and support the soil with a retaining wall, or to form them at an angle of 1 in 3 or 1 in 4.

An embankment—bank, or fill, is the reverse of a cutting, being an artificial mound of earth on which the railway is taken across depressions in the surface of the ground. An embankment is made so to plan the works of a railway that the quantity of earth excavated in cuttings shall be equal to the quantity required for the embankments; but this is not always practicable, and it is sometimes advantageous to obtain the earth from some source close to the embankment rather than incur the expense of hauling it from a distant cutting. As embankments have to support the weight of heavy trains, they must be uniformly firm and well drained, and before the line is fully opened for traffic they must be allowed time to consolidate, a process which is helped by running construction or mineral trains over them.

An interesting case of embankment and cutting in combination was presented by the crossing of Chat Moss on the Liverpool & Manchester railway. The moss was 4½ m. across, and it varied in depth from 10 to 30 ft. Its general character was such that cattle could not stand on it, and a piece of iron would sink in it. The subsoil was composed principally of clay and sand, and the railway had to be carried over the moss on the level, requiring cutting, and embanking for upwards of 4 m. In forming 277,000 cub. yds. of embankment 670,000 yds. of raw peat were consumed, the difference being occasioned by the squeezing out of the water. Large quantities of embanking were sunk in the moss, and, when the engineer, George Stephenson, after a month's vigorous operations, had made up his estimates, the apparent work done was sometimes less than at the beginning of the month. The railway ultimately was made to float on the bog. Where embanking was required drains 5 yds. apart were cut and when the moss between them was dry it was used to form the embankment. Where the way was formed on the level, drains were cut on each side of the intended line, and were intersected here and there by cross drains, by which the water of the moss was rendered dry and firm. Such an embankment was placed, 4 ft. broad and 9 long, covered with heath, upon which the ballast was laid.

**Bridges.—** For conveying small streams through embankments, channels or culverts are constructed in brickwork or masonry. Larger rivers, canals, roads, other railways and sometimes deep narrow valleys are crossed by bridges (q.v.) of timber, brick, stone, wrought iron or steel, and many of these structures rank among the largest engineering works in the world. Sometimes also a viaduct consisting of a series of arches is preferred to an embankment when the line has to be taken over a piece of flat alluvial plain, or when it is desired to economize space and to carry the line at a sufficient height to clear the streets, as in the case of various railways entering London and other large towns. In connexion with a railway many bridges have also to be constructed to carry public roads and other railways over the line, and for the use of owners or tenants whose land it has cut through ("accommodation bridges"). In the early days of railways, roads were often taken across the line on the level, but such "level" or "grade" crossings are now usually avoided in the case of new lines in populous countries, except when the traffic on both the road and the railway is very light. In many instances old level crossings have been replaced by over-bridges with long sloping approaches; in this way considerable expenditure has been avoided, justified, however, by the greater safety of the line and of its connections to the traffic on both the roads and the railways. In cases where the route of a line runs across a river or other piece of water so wide that the construction of a bridge is either impossible or would be more costly than is warranted by the volume of traffic, the expedient is sometimes adopted of carrying the wagons and carriages across bodily with their loads on train ferries, so as to avoid the inconvenience and delay of transhipment. Such train ferries are common in America, especially on the Great Lakes, and exist at several places in Europe, as in the Baltic between Denmark and Sweden and Denmark and Germany, and across the Straits of Messina.

**Gradients.—** The gradient or grade of a line is the rate at which it rises or falls, above or below the horizontal, and is expressed by stating either the horizontal distance in which the change of level amounts to 1 ft., or the amount of the rise or fall that would occur in some selected distance, such as 100 ft., 1000 ft., or 1 m. In America a gradient of 1 in 100 is often known as a 1% grade, one of 1 in 200 as a 0.5% grade, and so on; thus a 0.25% grade corresponds to what in England would be known as a gradient of 1 in 400. The ruling gradient of a section of railway is the steepest incline in that section, and is so called because it governs or rules the maximum load that can be placed behind an engine working over that portion of line. Sometimes, however, a sharp incline occurring on an otherwise easy line is not reckoned as the ruling gradient, trains heavier than could be drawn up it by a single engine being helped by an assistant or "bank" engine; sometimes also "momentum" or "velocity" grades, steeper than the ruling gradient, are permitted for short distances in cases where a train can approach at full speed and thus surmount them by the aid of its momentum. An incline of 1 in 400 is reckoned easy, of 1 in 200 moderate and of 1 in 100 heavy. The ruling gradient of the Liverpool & Manchester railway was fixed at 1 in 900, excepting the inclines at Liverpool and at Rainhill summit, for working which special provision was made; and I. K. Brunel laid out the Great Western for a long distance.
RAILWAYS

out of London with a ruling gradient of 1 in 330. Other engineers, however, such as Joseph Locke, cheapened the cost of construction by admitting long slopes of 1 in 80 or 70. One of the steepest gradients in England on an important line is the Lickey incline at Bromsgrove, on the Midland railway between Birmingham and Gloucester, where the slope is 1 in 37 for two miles. The maximum gradient possible depends on climatic conditions, a dry climate being the most favourable. The theoretical limit is about 1 in 15; between 1 in 20 and 1 in 16 a steam locomotive depending on the adhesion between its wheels and the rails can only haul about its own weight. In practice the gradient should not exceed 1 in 22, and even that is too steep, since theoretical conditions cannot always be realized; a wet rail will reduce the adhesion, and the gradients must be such that some paying load can be hauled in all weathers. When an engineer has to construct a railway up a hill having a still steeper slope, he must secure practicable gradients by laying out the line in ascending spirals, if necessary tunnelling into the hill, as on the St Gothard railway, or in a series of zigzags, or he must resort to a rack or a cable railway.

Rack Railways.—In rack railways a cog-wheel on the engine engages a rack on the rails, which renders vertical movement possible. The earliest arrangement of this kind was patented by John Blenkinsop, of the Middleton Colliery, near Leeds, in 1811, and an engine built on his plan by Matthew Murray, also of Leeds, began in 1812 to haul coal from the colliery to the main railway. Blenkinsop placed the teeth on the outer side of one of the running rails, and his reason for adopting a rack was the belief that an engine with smooth wheels running on smooth rails would not have sufficient adhesion to draw the load required. It was not till more than half a century later that an American, Sylvester Marsh, employed the rack system for the purpose of enabling trains to surmount steep slopes on the Mount Washington railway, where the maximum gradient was nearly 1 in 23. In this case the rack had pin teeth carried in a pair of the rails, forming a combination of rack and cog. A rack railway is essentially associated with a Swiss engineer, Nicholas Riggenbach, and his pupil Roman Abt, and the forms of rack introduced by them are those most commonly used. That of the latter is the most simple, several rack-plates being placed parallel to each other, and the teeth break joint at 34° or 45° of their pitch, according to the number of rack-plates. In this way smoothness of working is ensured, the cog-wheel being constantly in action with the rack. Abt's rack was the result of combining rack and cog, and in working, the engine working by adhesion alone on the gentler slopes but by both adhesion and the rack on the steeper ones. On such lines the beginning of a rack section is provided with a pair of cog-wheels, the springing of which prevents the rolling of the wheels over the rack. In the second type, the rack, employed on the Mount Pilatus railway, where the steepest gradient is nearly 1 in 2, is double, with vertical teeth on each side, while in the Scrub rack, used on the Jungfrau line, the teeth are cut in the form of a rack of the ordinary Vignoles type.

Cable Railways.—For surmounting still steeper slopes, cable railways may be employed. Of these there are two main systems: (1) a continuous cable is carried over two main drums at each end of the line, and the motion is derived either (a) from the weight of the descending load or (b) from a motor acting on one of the main drums; (2) each end of the cable is attached to wagons, one set of which accordingly ascends as the other descends. The weight required to cause the downward motion is obtained either by means of the cargo itself, or by the rolling of a water ballast, or by water ballast, while to aid and regulate the motion generally steam or electric motors are arranged to act on the main drums, round which the cable is passed with a sufficient number of turns to cause it to be hoisted to a height of 1,000 ft., the vessel being filled into a tank in the bottom of the wagon or car, its quantity, if passengers are carried, being regulated by the number ascending or descending.

Curves.—The curves on railways are either simple, when they consist of a portion of the circumference of a single circle, or compound, when they are made up of portions of the circumference of two or more circles of different radius. Reverse curves are compound curves in which the components are of contrary flexure, like the letter S; strictly the term is only applicable when the two portions follow directly one on the other, but it is sometimes used of cases in which they are separated by a "tangent" or portion of straight line. In Great Britain the curvature is defined by stating the length of the radius, expressed in chains (1 chain=66 ft., in America by stating the angle subtended by a chord 100 ft. long; the measurements in both methods are referred to the central line of the track. The radius of a 1-degree curve is 5730 ft., or about 86½ chains, of a 15-degree curve 383 ft. or rather less than 6 chains; the former is reckoned easy, the latter very sharp, at least for main lines on the standard gauge. On some of the earlier English main lines no curves were constructed of a less radius than one mile (80 chains), except at places where the speed was likely to be low, but in later practice the radius is sometimes reduced to 40 or 30 chains, even on high-speed passenger lines.

When a train is running round a curve the centrifugal force which comes into play tends to make its wheel-flanges press against the outer rail, or even to capsize it. If this pressure is not relieved in some way, the train may be derailed either (1) by "climbing" the outer rail, with injury to that rail and, generally, to the corresponding wheel-flanges; (2) by overturning about the outer rail as a hinge, possibly without injury to rails or wheels; or (3) by forcing the outer rail outwards, occasionally to the extent of shearing the spikes that hold it down at the curve, thus spreading or destroying the track. In any case the details depend upon whether the vehicle concerned is an engine, a wagon or a passenger coach, and upon whether it runs on bogie-trucks or not. If it is an engine, particular attention must be directed to the type, weight, arrangement of wheels and height of centre of gravity above rail level. In considering the forces that produce derailment the total mass of the vehicle or locomotive may be supposed to be concentrated at its centre of gravity. Two lines may be drawn from this point, one to each of the two rails, in a plane normal to the rails, and the ends of these lines, where they meet the rails, may be joined to complete a triangle, which may conveniently be regarded as a rigid frame resting on the rails. As the vehicle sweeps round the curve the centre of gravity tends to be thrown outwards, like a stone from a horizontal sling. The vertical pressure of the frame upon the outer rail is thus increased, while its vertical pressure on the inner rail is diminished. Simultaneously the frame as a whole tends to slide horizontally athwart the rails, from the inner towards the outer rail, urged by the same centrifugal forces. This sliding movement is resisted by placing a check rail on the inner side of the outer rail, to take the lateral thrust of the wheels on that side. It is also resisted in part by the conicity of the wheels, which converts the lateral force partly into a vertical force, thus enabling gravity to exert a restoring influence. When the lateral forces are too great to be controlled "climbing" occurs. Accidents due to simple climbing are, however, exceedingly rare, and are usually found associated with a faulty track, with "plunging" movements of the locomotive or vehicle, or with a "tight gauge" at curves or points.

From consideration of the rigid triangular frame described above, it is clear that the "overturning" force acts horizontally from the centre of gravity, and that the length of its lever arm 45. Since of course the same must be true of the force due to gravity acting in a vertical line from the centre of gravity, the lever arm is the horizontal distance between this vertical line and the outer rail. If therefore the outer rail is laid at a level above that of the inner rail at the curve, overturning will be resisted more than would be the case if both rails were in the same horizontal plane, since the tilting of the vehicle due to this "supererelevation" diminishes the overturning moment, and also increases the restoring moment, by shortening in the one case and lengthening in the other the lever arms at which the respective forces act. The amount of supererelevation required to prevent derailment on a curve can be calculated under perfect running conditions, given the radius of curvature, the weight of the vehicle, the height of the centre of gravity, the distance between the rails, and the speed; but great experience 3 See The Times Engineering Supplement (August 22, 1906), p. 265.****
is required for the successful application of definite formulae to the problem. For example, what is a safe speed at a given curve for an engine, truck or coach having the load equally distributed over the wheels may lead to either climbing or overturning if the load is shifted to a diagonal position. An ill-balanced load also exaggerates "plunging," and if the period of oscillation of the load happens to agree with the changes of contour or other inequalities of the track vibrations of a dangerous character, giving rise to so-called "sinuous" motion, may occur.

In general it is not curvature, but change of curvature, that presents difficulty in the laying-out of a line. For instance, if the curve is of S-form, the point of danger is when the train enters the contra-flexure, and it is not an easy matter to assign the best supererelevation at all points throughout the double bend. Closely allied to the question of safety is the problem of preventing jolting at curves; and to obtain easy running it is necessary not merely to adjust the levels of the rails in respect to one another, but to tail off one curve into the next in such a manner as to avoid any approach to abrupt lateral changes of direction. With increase of speeds this matter has become important as an element of comfort in passenger traffic. As a first approximation the center of curvature of a railway line is taken as a number of portions of circles, with intervening straight tangents connecting them, when the abruptness of the changes of direction will depend on the radii of the circular portions. But if the change from straight to circular is made through the medium of a suitable curve it is possible to relieve the abruptness, even on curves of comparatively small radius. The smoothest and safest running is, in fact, attained when a "transition," "easement" or "adjustment" curve is inserted between the tangent and the point of circular curvature.

Gauge.—The gauge of a railway is the distance between the inner edges of the two rails upon which the wheels run. The width of 4 ft. 8 1/2 in. may be regarded as standard, since it prevails on probably three-quarters of the railways of the globe. In North America, except for small industrial railways and single-section lines for local traffic, chiefly in mountainous country, it has become almost universal; the long lines of 3 ft. gauge have mostly been converted, or a third rail has been laid to permit interchange of vehicles, and the gauges of 5 ft. and more have disappeared. A considerable number of lines still use 4 ft. 9 in., but as their rolling stock runs freely on the 4 ft. 8 1/2 in. gauge and vice versa, this does not constitute a break of gauge for traffic purposes. The commercial importance of such free interchange of traffic is the controlling factor in determining the gauge of any new railway that is not isolated by its geographical position. In Great Britain railways are built to gauges other than 4 ft. 8 1/2 in. only under exceptional conditions; the old "broad gauge" of 7 ft. which J. K. Brunel adopted for the Great Western railway disappeared on the 26th-23rd of May 1892, when the main line from London to Penzance was converted to standard gauge throughout its length. In Ireland the usual gauge is 5 ft. 3 in., but there are also lines laid to a 3 ft. gauge. On the continent of Europe the standard gauge is generally adopted, though in France there are many miles of 4 ft. 9 in. gauge; the normal Spanish and Portuguese gauge is 3 ft.; and that of Russia 5 ft. In France and other European countries there is also an important mileage of metre gauge, and even narrower, on lines of local or secondary importance. In India the prevailing gauge is 5 ft. 6 in., but there is a large mileage of other gauges, especially metre. In the British colonies the prevailing gauge is 3 ft. 6 in., as in South Africa, Queensland, Tasmania and New Zealand; but in New South Wales the normal is 4 ft. 8 1/2 in. and in Victoria 5 ft. 3 in., communication between different countries of the Australian Commonwealth being thus carried on under the disadvantage of break of gauge. Though the standard gauge is in use in Lower Egypt, the line into the Egyptian Sudan was built on a gauge of 3 ft. 6 in., so that if the so-called Cape to Cairo railway is ever completed, there will be one gauge from Upper Egypt to Cape Town. In South America the 5 ft. 6 in. gauge is in use, with various others.

Mono-Rail Systems.—The gauge may be regarded as reduced to its narrowest possible dimensions in mono-rail lines, where the weight of the trains is carried on a single rail. This method of construction, however, has been adopted only to a very limited extent. In the Laritique system the train is straddled over a single central rail, elevated a suitable distance above the ground. A short line of this kind runs from Ballybunnion to Listowel in Ireland, and a more ambitious project on the same principle, on the plans of Mr F. B. Behr, to connect Liverpool and Manchester, was sanctioned by Parliament in 1901. In this case electricity was to be the motive-power, and speeds exceeding 100 m. an hour were to be attained, but the line has not been built. In the Langen mono-rail the cars are hung from a single overhead rail; a line on this system works between Barmen and Elberfeld, about 9 m., the cars for a portion of the distance being suspended over the river Wupper. In this case devised by Mr Louis Brennan the cars run on a single rail laid on the ground, their stability being maintained by a heavy gyrostat revolving at great speed in a vacuum.

Permanent Way.—When the earth-works of a line have been completed and the tops of the embankments and the bottoms of the cuttings brought to the level decided upon, the next step is to lay the permanent way, so-called probably in distinction to the temporary way used during construction. The first step is to deposit a layer of ballast on the road-bed or "formation," which often slopes away slightly on each side from the central line to facilitate drainage. The ballast consists of such materials as broken stone, furnace slag, gravel, cinders or earth, the lower layers commonly consisting of coarser materials than the top ones, and its purpose is to provide a firm, well-drained foundation in which the sleepers or cross-ties may be embedded and held in place, and by which the weight of the track and the trains may be distributed over the road-bed. Its depth varies, according to the traffic which the line has to bear, from about 6 in. to 1 ft. or rather more under the sleepers, and the materials of the surface layers are often chosen so as to be more or less dustless. Its width depends on the numbers of tracks and their gauge; for a double line of standard gauge it is about 25 ft., a space of 6 ft. ("six-foot way") being left between the inner rails of each pair in Great Britain (fig. 8), and a rather larger distance in America (fig. 9), where the over-hang of the rolling stock is greater. The intervals between the sleepers are filled in level with ballast,
Sleepers, called ties or cross-ties in America, are the blocks or slabs on which the rails are carried. They are nearly always placed transversely, across the direction of the lines, the longitudinal position such as was adopted in connexion with the broad gauge on the Great Western in England having been abandoned except in special cases. Stone blocks were tried as sleepers in the early days of railways, but they proved too rigid, and besides, it was found difficult to keep the line true with them. Wood is the material most widely used, but steel is employed in some countries where timber is scarce or liable to destruction by white ants, though it is still regarded as too expensive in comparison with wood for general adoption. Steel sleepers were used experimentally on the London & North-Western, but were abandoned owing to the shortness of their life. In Germany, where they have met with greater favour, there were over 26½ millions in use in 1905, and they have been tried by some American railways. Numerous forms of ferro-concrete sleepers have also been devised. In Great Britain, Germany and France, at least 90% of the wooden sleepers are "treated" before they are laid, to increase their resistance to decay, and the same practice is followed to some extent in other European countries. A great number of preservative processes have been devised. In that most largely used, known as "creosoting," dead oil of tar, to the amount of some 3 gallons per sleeper, is forced into the wood under pressure, or is sucked in by vacuum, both the timber and the oil being heated. In the United States only a small percentage of the ties are treated in any way beyond seasoning in the open air, timber, in the opinion of the railway officials, being still too cheap in nearly all parts of that country to justify the use of preservatives. Some railway companies, however, having a long mileage in timberless regions, do "treat" their sleepers.

Typical dimensions for sleepers on important British railways are:—length 9 ft., breadth 10 in., and depth 5 in. In America 8 ft. is the most common length, the breadth being 8 in., and the depth 6 or 7 in.

There are two main ways of attaching the rails to the sleepers, corresponding to two main types of rails—the bull-headed rail and the Vignoles or flange rail. In the first method, which is practically universal in Great Britain and is also employed to some extent in France and India, the rails have rounded bases and are supported by being wedged, with wooden keys, in cast-iron chairs which are bolted to the sleepers. In the second method the rails have flat flanged bases which rest directly on the sleepers (fig. 10). The chairs on the British system weigh about 45 or 50 lb each on important lines, though they may be less where the traffic is light, and are fixed to the sleepers each by two, three or four fastenings, either screw spikes, or round drift bolts entered in holes previously bored, or Fang bolts or wooden trenails. Sometimes a strip of felt is interposed between the chair and the sleeper, and sometimes a serrated surface is prepared on the sleeper for the chair which is forced into its seat by hydraulic pressure. The keys which hold the rail in the chairs are usually of oak and are placed outside the rails; the inside position has also been employed, but has the disadvantage of detracting from the elasticity of the road since the weight of a passing train presses the rails up against a rigid mass of metal instead of against a slightly yielding block of wood. The rails, which for heavy main line traffic may weigh as much as 100 lb per yard, or even more, are rolled in lengths of from 30 to 60 ft., and sleepers are placed under them at intervals of between 2 and 3 ft. (centre to centre). 12 sleepers to a 30 ft. rail being a common arrangement. On the London & North-Western railway there are 24 sleepers to each 60 ft. rail. A small space is left between the end of one rail and that of the next, in order to allow for expansion in hot weather, and at the joint the two are firmly braced together by a pair of fish-plates (fig. 11). These are flat bars of iron or steel from 18 in. to 2 ft. long, which are lodged in the channels of the rail, one on each side, and secured with four bolts passing through the web; sometimes, to give additional stiffness, they extend down below the lower table of the rail and are bent round so as to clip it. Occasionally the joints thus formed are "supported" on a sleeper, as was the practice in the early days of railway construction, but they are generally "suspended" between two sleepers, which are set rather more closely together than at other points in the rail. Preferably, they are so arranged that those in both lines of rails come opposite each other and are placed between the same pair of sleepers.

Flat-bottomed rails are fastened to the sleepers by hook-headed spikes, the heads of which project over the flanges. In the United States the spikes are simply driven in with a maul, and the rails stand upright, little care being taken to prepare seats for them on the sleepers, on which they soon seat themselves. The whole arrangement is simple and cheap in first cost, and it lends itself admirably to fast track-laying and to repairs and changes of line. On the continent of Europe the practice is common of notching the sleeper so as to give the rail a slight cant inward, and in England by canting the rail in the chairs—and metal plates or strips of felt are put under the rail, which is carefully fastened to the sleeper by screwed spikes (fig. 12). This method of construction is more expensive than the American in first cost, but it gives a more durable and stable track. Such metal plates, or "tie-plates," have come into considerable use also in the United States, where they are always made of rolled steel, punched with rectangular holes through which the spikes pass. They serve two principal...
purposes: they diminish the wear of the sleeper under the rail by providing a larger bearing surface, and they help to support the spikes and so to keep the gauge. On all the accepted forms there are two or more flanges at the bottom, running lengthwise of the plate and crosswise of the rail; these are requisite to give proper stiffness, and further, as they are forced into the tie by the weight of passing traffic, they help to fix the plate securely in place. The joints of flanged rails are similar to those employed with bull-headed rails. Various forms, mostly patented, have been tried in the United States, but the one most generally adopted consists of two symmetrical angle bars (fig. 13), varying in length (from 20 to 48 in.), in weight and in the number of bolts, which may be four or six.

The substitution of steel for iron as the material for rails which made possible the axle loads and the speeds of to-day, and, by reducing the cost of maintenance, contributed enormously to the economic efficiency of railways, was one of the most important events in the history of railways, and a scarcely less important element of progressive economy has been the continued improvement of the steel rail in stiffness of section and in toughness and hardness of material. Carbon is the important element in controlling hardness, and the amount present is in general higher in the United States than in Great Britain. The specifications for bull-headed rails issued by the British Engineering Standards Committee in 1904 provided for a carbon-content ranging from 0.35 to 0.50%, with a phosphorus maximum of 0.075%. In the United States a committee of the American Society of Civil Engineers, appointed to consider the question of rail manufacture in consequence of an increase in the number of rail-failures, issued an interim report in 1907 in which it suggested a range of carbon from 0.55 to 0.65% for the heaviest sections of Bessemer steel flange rails, with a phosphorus maximum of 0.085%; while the specifications of the American Society for Testing Materials, current at the same period, put the carbon limits at 0.45 to 0.55%, and the phosphorus limit at 0.10. For rails of basic open-hearth steel, which is rapidly ousting Bessemer steel, the Civil Engineers’ specifications allowed from 0.65 to 0.75% of carbon with 0.05% of phosphorus, while the specifications of the American Railway Engineering and Maintenance of Way Association provided for a range of 0.75 to 0.85% of carbon, with a maximum of 0.03% of phosphorus. The rail-failures mentioned above also draw renewed attention to the importance of the thermal treatment of the steel from the time of melting to the last passage through the rolling mill and to the necessity of the finishing temperature being sufficiently low if the product is to be fine grained, homogeneous and tough; and to permit of this requirement being met there was a tendency to increase the thickness of the metal in the web and flanges of the rails. The standard specification adopted by the Pennsylvania railway in 1908 provided that in rails weighing 100 lb to the yard 41% of the metal should be in the head, 18-6% in the web, and 40-4% in the base, while for 85 lb rails 42.2% was to be in the head, 17.8% in the web and 40.0% in the base. The rails were to be rolled in 33 lengths. According to the specification for 85 lb rails adopted by the Canadian Pacific railway about the same time, 36.77% of the metal was to be in the head, 22.21% in the web and 41.02% in the base.

Points and Crossings.—To enable trains to be transferred from one pair of rails to another pair, as from the main line to a siding, “points” or “switches” are provided. At the place where the four rails come together, the two inner ones (one of the main line and the other of the siding), known as “switch rails” (b, fig. 14), are tapered to a fine point or tongue, and rigidly connected together at such a distance apart that when one of the points is pressed against the outer or “stock” rail (a) of either the siding or the main line there is sufficient space between the other tongue and the other stock rail to permit the free passage of the flanges of the wheels on one side of the train, while the flanges on the other side find a continuous path along the other switch rail and thus are deflected in the desired direction. The same arrangement is employed at junctions where different running lines converge. The points over which a train travels when directed from the main to a branch line are called “facing points” (FP), while those which it passes when running from a branch to a main line are “trailing points” (TP). In Great Britain the Board of Trade requires facing points to be avoided as far as possible; but, of course, they are a necessity at junctions where running lines diverge and at the crossing places which must be provided to enable trains to pass each other on single-track lines. At stations the points that give access to sidings are generally arranged as trailing points with respect to the direction of traffic on the main line that is to say, trains do not pass direct into sidings, but have to stop and then run backwards into them. In shunting yards the points are commonly set in the required direction by means of hand levers placed close beside the lines, but those at junctions and those which give access from the main lines to sidings at wayside stations are worked by a system of rods from the signal cabin, or by electric or pneumatic power controlled from it and interlocked with the signals (see Signal: § Railway). Crossings are inevitable adjacents of points. Where a branch diverges from a main line, one rail of the one must cross one rail of the other, and a V-crossing is formed (V). Where, as at a double-line junction, one pair of rails crosses another pair, “diamond” crossings (D) are formed. At both types of crossing, check rails (c) must be provided to guide the wheel-flanges, and if these are not accurately placed the safety of the trains will be endangered. At double-line junctions trains passing over the diamond crossings evidently block traffic going in the opposite direction to that in which they are travelling. To avoid the delay thus caused the diamond crossing if it were taken across the level is sometimes carried over the main line by an over-bridge (“flying junction”) or under it by an under-bridge (“burrowing junction”).

Railway Stations.—Railway stations are either “terminal” or “intermediate.” A terminal station embraces (1) the passenger station; (2) the goods station; (3) the locomotive, carriage and wagon depots, where the engines and the carrying stock are kept, cleaned, examined and repaired. At many intermediate stations the same arrangements, on a smaller scale, are made; in all of them there is at least accommodation for the passenger and the goods traffic. The stations for
passengers and goods are generally in different and sometimes in distant positions, the place selected for each being that which is most convenient for the traffic. The passenger station abuts on the main line, or, at termini, forms the natural terminus, at a place as near as conveniently can be obtained to the centre of the population which constitutes the passenger traffic; and preferably its platforms should be at or near the ground level, to facilitate access. The goods station is approached by a siding or fork set off from the main line at a point short of the passenger station. In order to keep down the expense of shutting the empty trains and engines to and from the platforms the carriage and locomotive depots should be as near the passenger station as possible; but often the price of land makes it impracticable to locate them in the immediate vicinity and they are to be found at a distance of several miles.

In laying out the approaches and station yard of a passenger station ample width and space should be provided, with well-defined means of ingress and egress to facilitate the circulation of vehicles and with a long setting-down pavement to enable them to discharge their passengers and luggage without delay. The position of the main buildings—ticket offices, waiting and refreshment-rooms, parcels offices, &c.—relative to the direction of the lines of traffic may be used as a means of classifying terminal stations. They are placed either on the departure side parallel to the platform ("side stations") or at right angles to the main lines ("end stations"). Many large stations, however, are of a mixed type, and the offices are arranged in a fork between two or more series of platforms, or partly at the end and partly on one side. Where heavy suburban traffic has to be dealt with, the expedient is occasionally adopted of taking some of the lines round the end in a continuous loop, so that incoming trains can deposit their passengers at an underground platform and immediately proceed on their outward journey. Intermediate stations, like terminal ones, should be convenient in situation and easy of approach, and, especially if they are important, should be on the ground level rather than on an embankment or in a cutting. The lines through them should be, if possible, straight and on the level; the British Board of Trade forbids them being placed on a gradient steeper than 1 in 250, unless it is unavoidable. Intermediate stations at the surface level are naturally constructed as side stations, and whether offices are provided on both sides or whether they are mainly concentrated on one will depend on local circumstances, the amount of the traffic, and the direction in which it preponderates. When the railway lies below the surface level the bulk of the offices are often placed on a bridge spanning the lines, access being given to the platforms by staircases or lifts, and similarly when the railway is at a high level the offices may be arranged under the lines. Occasionally on a double-track railway one platform placed between the tracks serves both of them; this "island" arrangement, as it is termed, has the advantage that more tracks can be readily added without disturbance of existing buildings, but when it is adopted the exit from the tracks is at the opposite side to that which is usual, and accidents have happened through passengers alighting at the usual side without noticing the absence of a platform. At stations on double-track railways which have a heavy traffic four tracks are sometimes provided, the two outside ones only having platforms, so that fast trains get a clear road and can pass slow ones that are standing in the station. In Great Britain, it may be noted, trains almost invariably keep to the left, whereas in most other countries right-handed running is the rule.

The arrangement and provision of the tracks in a station materially affect the economical and efficient working of the traffic. There must be a sufficient provision of sidings, connected with the running tracks by points, for holding spare rolling stock and to enable carriages to be added to or taken off trains and engines to be changed with as little delay as possible. At terminal stations, especially as such are used by short-distance trains which arrive at and start from the same platform, a third track is often laid between a pair of platform tracks, so that the engine of a train which has arrived at the platform can pass out and place itself at the other end of the train, which remains undisturbed. At the new Victoria station (London) of the London, Brighton & South Coast railway—which is so long that two trains can stand end to end at the platforms—this system is adopted so as to permit a train to start out from the inner end of a platform even when another train is occupying the outer end. One of the advantages of electric trains on the multiple control system is that they economize terminal accommodation, because they can be driven from either end indifferently, and therefore avoid the necessity for tracks on which engines can change from one end of the train to the other.

The platforms on British railways have a standard elevation of 3 ft. above rail level, and they are not now made less than 2 ft. in height. In other countries they are generally lower; in the United States they are commonly level with, or only a few inches higher than, the top of the rails. They may consist of earth with a retaining wall along the tracks and with the surface gravelled or paved with stone or asphalt, or they may be constructed entirely of timber, or they may be formed of stone slabs supported on longitudinal walls. They should be of ample dimensions to accommodate the traffic—the British Board of Trade requires them to be not less than 6 ft. wide at small stations, and 8 ft. and more at principal stations. They should be as free as possible from obstructions, such as pillars supporting the roof. At intermediate stations the roofs are often carried on brackets fixed to the walls of the station buildings, and project only to the edge of the platforms. At larger stations where both the platforms and the tracks are covered, there are two broad types of construction, with many intermediate variations: the roof may either be comparatively low, of the "ridge and furrow" pattern, borne on a number of rows of pillars, or it may consist of a single lofty span extending clear across the area from the side walls. The advantage claimed for roofs formed with one or two large spans is that it permits the platforms and tracks to be readily rearranged at any time as required, whereas this is difficult with the other type, especially since the British Board of Trade requires the pillars to be not less than 6 ft. away from the edges of the platforms. On the other hand, wide spans are more expensive both in first cost and in maintenance, and there is the possibility of a failure such as caused the collapse in December 1905 of the roof of Charing Cross (S.E.R.) station, London, which then consisted of a single span. Whatever the pattern adopted for the roof, a sufficient portion of it must be glazed to admit light, and it should be so designed that the ironwork can be easily inspected and painted and the glass readily cleaned. For the illumination of large stations by night electric arc lamps are frequently employed, but some stations favour high-pressure incandescent gas lighting.

At busy stations separate tracks are sometimes appropriated to the use of light engines and empty trains, on which they may be run between the platforms and the locomotive and carriage depots. A carriage depot includes sheds in which the vehicles are stored, arrangements for washing and cleaning them, and sidings on which they are marshalled into trains. At a locomotive depot the chief building is the "running shed" in which the engines are housed and cleaned. This may be rectangular in shape ("straight" shed), containing a series of parallel tracks on which the engines stand and which are reached by means of points and crossings diverging from a main track outside; or it may take a polygonal or circular form (round house or rotunda), the lines for the engine roads being laid in parallel lines and in parallel circles on a large radius and can be rotated so as to serve any of the radiating lines. The second arrangement enables any particular engine to enter or leave without disturbing the others, but on the other hand an accident to the turn-table may temporarily impoin the whole of them. In both types pits are constructed between the rails
RAILWAYS

on which the engines stand to afford easy access for the inspection and cleaning of their mechanism. Machine shops are usually provided to enable minor repairs to be executed; the tendency both in England and America, is to increase the amount of such repairing plant at engine sheds, thus lengthening the intervals between the visits of the engines to the main repairing shops of the railway. A locomotive depot further includes stores of the various materials required in working the engines, coal stages at which they are loaded with coal, and an ample supply of water. The quality of the last is a matter of great importance; when it is unsuitable, the boilers will suffer, and the installation of a water-softening plant may save more in the expenses of boiler maintenance than it costs to operate. The water cranes or towers which are placed at intervals along the railway to supply the engines with water require similar care in regard to the quality of the water laid on to them, as also to the water troughs, or track tanks as they are called in America, by which engines are able to pick up water without stopping. These consist of shallow troughs about 18 in. wide, placed between the rails on perfectly level stretches of line. When water is required, a scoop is lowered into the trough behind the engine, and if the supply is sufficient the water is forced up into the tender-tanks. Such troughs were first employed on the London & North-Western railway in 1857 by John Ramsbottom, and have since been adopted on many other lines.

Goods stations vary in size from those which consist of perhaps a single siding, to those which have accommodation for thousands of wagons. At a small roadside station, where the traffic is of a purely local character, there will be some sidings to which horses and carts have access for handling bulk goods like coal, gravel, manure, &c., and a covered shed for loading and unloading packages and materials which is undesirable to expose to the weather. The shed may have a single pair of rails for wagons running through it along one side of a raised platform, there being a roadway for carts on the other side; or if more accommodation is required there may be two tracks, one on each side of the platform, which is then approached by carts at the end. In either case the platform is fitted with a crane or cranes for lifting merchandise into and out of the wagons, and doors enable the shed to be used as a lock-up warehouse. In a large station the arrangements become much more complicated, the precise design being governed by the nature of the traffic that has to be served and by the physical configuration of the site. It is generally convenient to keep the inwards and the outwards traffic distinct and to deal with the two classes separately; at junction stations it may also be necessary to provide for the transfer of freight from one wagon to another, though the bulk of goods traffic is conveyed through to its destination in the wagons into which it was originally loaded. The increased loading space required in the sheds is obtained by multiplying the number and the length of lines and platforms; sometimes also there are short sidings, cut into the platforms at right angles to the lines, in which wagons are placed by the aid of wagon turn-tables, and sometimes the wagons are dealt with on two floors, being raised or lowered bodily from the ground by jacks. There are also dock-connected warehouses where traders may store goods which have arrived or are awaiting despatch. An elaborate organization is required to keep a complete check and record of all the goods entering and leaving the station, to ensure that they are loaded into the proper wagons according to their destination, that they are unloaded and sorted in such a way that they can be delivered to their consignees with the least possible delay, that they are not stolen or accidentally mislaid, &c.; and accommodation must be provided for a large clerical and supervisory staff to attend to these matters. British railways also undertake the collection and delivery of freight, in addition to transporting it, and thus an extensive range of vans and wagons, whether drawn by horses or mechanically propelled, must be provided in connexion with an important station.

Shunting Yards.—It may happen that from a large station sufficient traffic may be consigned to certain other large stations to enable full train-loads to be made up daily, or several times a day, and despatched direct to their destinations. In general, however, the conditions are less simple. Though a busy colliery may send off its product by the train-load to an important town, the wagons will usually be addressed to a number of different consignees at different depots in different parts of the town, and therefore the train will have to be broken up somewhere short of its destination and its trucks rearranged, together with those of other trains similarly constituted, into fresh trains for conveyance to the various depots. Again, a station of moderate size may collect goods destined for a great variety of places but not in sufficient quantities to compose a full train-load for any of them, and then it becomes impossible, except at the cost of uneconomical working, to avoid despatching trains which contain wagons intended for many diverse destinations. For some distance these wagons will all travel over the same line, but sooner or later they will reach a junction-point where their ways will diverge and where they must be separated. At this point trains of wagons similarly destined for different places will be arriving from other lines, and hence the necessity will arise of collecting together from all the trains all the wagons which are travelling to the same place.

The problem may be illustrated diagrammatically as follows (fig. 15). A may be supposed to be a junction outside a large seaport where branches from docks a, b, c, and d converge, and where the main line also divides into three, going to B, C and D respectively. A train from a will contain some wagons for B, some for C and some for D, as will also the trains from a, b, c and d. At A therefore it becomes necessary to disentangle and group together all the wagons that are intended for B, all that are intended for C, and all that are intended for D. Even that is not the whole of the problem. Between A and B, A and C, and A and D, there may be a string of stations, p, q, r, s, &c., all receiving goods from a, b, c and d, and it would manifestly be inconvenient and wasteful of time and trouble if the trains serving those intermediate stations were made up with, say, six wagons from a to p next the engine, five from b to q at the middle, and four from c to r near the end. Hence at A the trucks from a, b, c and d must not only be sorted according as they have to travel along A B, A C, or A D, but also must be marshalled into trains in the order of the stations along those lines. Conversely, trains arriving at A from B, C and D must be broken up and remade in order to distribute their wagons to the different docks.

To enable the wagons to be shunted into the desired order a large number of sidings are constructed at important junction points like A. Such a yard consists essentially of a group or groups of sidings, equal in length at least to the longest train run on the line, branching out from a single main track and often again converging to a single track at the other end; the precise design, however, varies with the amount and character of the work that is to be done, with the configuration of the ground, and also with the method of shunting adopted. The oldest and commonest method of shunting is that known as "push-and-pull," or in America as "link-and-pin" or "tail" shunting. An engine coupled to a batch of wagons runs one or more of them down one siding, then returns back with the remainder clear of the points where the sidings diverge, runs one or more others down another siding, and so on till they are all disposed of. The same operation is repeated with fresh batches of wagons, until the sidings contain all the wagons intended to be shunted. In some cases nothing more is required than to attach an engine and brake-van ("caboose") and despatch the train; but if, as will happen in others, a further rearrangement of sides is necessary, the common practice is to employ a different design or method of shunting, as illustrated by other diagrams in this article.

Ara 15.—Diagram to illustrate use of Shunting Yards.
the wagons is necessary to get them into station order this is effected on the same principle.

Push-and-pull shunting is simple, but it is also slow, and therefore efforts have been made at busy yards where great numbers of trains are handled, to provide more expeditious methods. One of these, employed in America, is known as "poling." Alongside the tracks on which stand the trains that are to be broken up and from which the sidings diverge subsidiary tracks are provided for the shunting engines. These lines have a pole projecting horizontally in front of them, or are attached to a pole having such a pole. The method of working is for the pole to be swung out behind a number of wagons; one engine is then started, and it is run at a speed sufficient to carry them over the points, where they are diverted into any desired siding. It then runs back to the train to repeat the operation, while it is doing so a second engine similarly assignment, is run at a speed sufficient to carry them over the points and is then diverted into any desired siding. If these engines have a pole projecting horizontally in front of them, or are attached to a pole having such a pole, the method of working is for the pole to be swung out behind a number of wagons; one engine is then started, and it is run at a speed sufficient to carry them over the points, where they are diverted into any desired siding. It then runs back to the train to repeat the operation, while it is doing so a second engine similarly assigned is run at a speed sufficient to carry them over the points and is then diverted into any desired siding.

Another method, which was introduced into America from Europe about 1890, is that of the summit or "hump." The wagons are pushed by an engine at their rear up one slope of an artificial mound, and as they run down the other slope by gravity are switched into the desired siding. Sometimes a site can be found for the incline where the natural slope of the ground is sufficiently steep to make the wagons run down of themselves. One of the best known of such " gravity" yards is that at Edgehill, near Liverpool, on the London and South Western Railway, and it was established there in 1886. Here, at the highest level, there is a number of "upper reception lines" converging to a single line which leads to a group of "sortings sidings" at a lower level. These in turn converge to a pair of single lines which lead to two groups of marshalling sidings, called "lower sortings." From the shape, and these again converge to single lines leading to "lower reception and departure lines" at the bottom of the slope. The wagons from the upper reception lines are sorted into trains on the sorting sidings, and then, in the sidings, are arranged in the appropriate order andmarshalled ready to be sent off from the departure lines.

### Locomotive Power

The term "power" is used in technical sense to mean the rate at which work is done against a resistance, and is measured in units of energy expended per unit of time. The unit of power commonly used by engineers is the horse-power, and this unit corresponds to a rate of working of 550 foot-lb of work per second.

The problems arising out of the special consideration of the power required to propel a railway train against the resistances opposing its motion, the way the power is applied to trains, the agent by means of which the power is exerted, are conveniently grouped together under the general heading of Locomotive Power. There are certain fundamental relations common to all tractive problems, and these are briefly considered in §§ 1 and 2, after which the argument refers particularly to steam locomotives, although §§ 4, 5, 7, 8, 9, and 10 have a general application to all modes of traction.

#### § 1. Fundamental Relations

The resistance against which a train is moved along a railway is either by means of energy obtained from the combustion of fuel, or in some few cases by energy obtained from a waterfall. If the total resistance against which the train is maintained in motion with an instantaneous velocity of V feet per second is R, the rate at which energy is expended in moving the train is represented by the product RV, and this must be the rate at which energy is supplied to the train after deducting all losses due to transmission from the source of power. Thus if R is equal to 10,000 lb when the velocity is 44 ft. per second, equivalent to 30 m. per hour, the rate of working against the resistance is 440,000 foot-lb per second.

In whatever form energy is produced and distributed to the train it ultimately appears as mechanical energy applied to turn one or more axles against the resistance to their rotation imposed by the weight on the wheels and the motion of the train. The rate at which work is done on a particular axle is measured by the product Tw, where T is the torque or turning moment exerted on the axle by the motor or mechanism applied to it for this purpose, and w is the angular velocity of the axle in radians per second. Hence if all the energy supplied to the train is utilized at one axle there is the fundamental relation

$$ T_w = R V $$

Continuing the above arithmetical illustration, if the wheels of the axle of which the torque is applied are 4 ft. diameter, $\omega = 44/2 = 22$ radians per second, and therefore $T = 440,000/22 = 20,000$ lb ft. If the energy supplied is distributed between several axles the relation becomes

$$ T_{w1} + T_{w2} + T_{w3} + \ldots = RV $$

where $T_1$, $T_2$, $T_3$, &c. are the torques on the axles whose respective angular velocities are $\omega_1$, $\omega_2$, &c.

The fundamental condition governing the design of all tractive machinery is that the wheels belonging to the axles to which torque is applied shall roll along the rails without slipping, and exert a tractive force on the train.

The fundamental relation of motion between the applied torque and the tractive force $F$ will be understood from Fig. 16, which shows in a diagrammatic form a wheel and axle connected to the framework of a passenger coach. The nature of the coupling for railway trains. The journal of the axle A, is carried in a bearing or axle-box B, which is free to move vertically in the vertical slot G, formed in the frame, and called generally "the horns," under the control of the spring. The weight $W_1$ carried by the part of the frame supported by the wheel (whose diameter is D) is transmitted first to the pins $P_1$, $P_2$, which are fixed to the frame, and then to the spring links $L$, which are jointed at their respective ends to the spring $S$, the centre of which rests on the axle-box. Let a couple be applied to the axle tending to turn it in the direction shown by the arrow. This couple, we may assume, will be equally divided between the two wheels, so that the torque acting on each will be $\frac{T}{2}$. Assuming that the wheels will roll along the rail without slipping, this couple will be equivalent to the couple formed by the equal opposite and parallel forces, $P_1$, acting in the direction shown, from the axle-box on to the frame, and $F_1 = \omega_1$, acting along the rail. The torque corresponding to this couple is $F_1 \times D = \frac{T}{2} \times D$, and hence follows the fundamental relation, $T = \frac{1}{2} F_1 D = \frac{1}{2} W_1 D$, or $T = \frac{1}{2} W_1 D F_1$, which expresses the work supported by the axle, $F_1$ will be the tractive force exerted on the frame by the two axle-boxes to propel the vehicle, and the more convenient relation is established:

$$ T = \frac{1}{2} F_1 D W_1 $$

If $T$ has a greater value than this relation justifies the wheels will slip. $F_1$ is called the "tractive force" at the rail. The coefficient of friction $\mu$ is a variable quantity depending upon the state of the rails, and is usually taken to be . This is the fundamental equation between the forces acting, however the torque may be applied. Multiplying through by $\omega_1$ we obtain

$$ T \omega_1 = \frac{1}{2} F_1 D \omega_1 W_1 D = RV $$

This is a fundamental energy equation for any form of locomotive in which there is only one driving-axe.

The couple $T$ is necessarily accomplished by an equal and opposite couple on the frames on which each couple endeavours to turn the frame in the opposite direction to that in which the axle rotates. The practical effect of this opposite couple is slightly to tilt the frame and thus to redistribute slightly the weights on the wheels carrying the vehicle.

If there are several driving-axes in a train, the product $T \omega_1$ must be estimated for each separately; then the sum of the products will be equal to RV. In equation (4) there is a fixed relation between $\omega_1$, $V$ and D given by the expression

$$ \omega_1 = \frac{2V}{D} $$

Here $D$ is in feet, $V$ in feet per second and $\omega_1$ in radians per second. If the speed is given in miles per hour, $V$ say,

$$ \omega_1 = \frac{V}{11} $$

The revolutions of the axle per second, $n$, are connected with the radians turned through per second by the relation

$$ n = \frac{\omega_1}{2\pi} = \frac{V}{60 \times 38} $$

#### § 2. Methods of Applying Locomotive Power

By locomotive power is to be understood the provision of power to maintain the rates of working on the driving-axes of a train indicated by the relation (4). The most usual way of providing this power is by the combustion of fuel in the furnace of a boiler and the utilization of the steam produced in a steam-engines, both boiler and engine being carried on a frame mounted on wheels in such a way that the crank-shaft of the steam-engine becomes the driving-axe of the train. From equation (3) it is clear that the wheels of the driving-axe must be heavily loaded in order that $F_1$ may have a value sufficiently great to propel the train. The maximum weight which one pair of wheels is usually allowed to carry on a first-class track is from 18 to 20 tons. If a larger
value of the tractive force is required than this provides for, namely from 4 to 5 tons, the driving-wheels are coupled to one or more driving-axles, or loaded wheels forming a class of what are called “coupled engines” in contradistinction to the “single engine” with a single pair of loaded driving-wheels. Mechanical energy may be developed in bulk at a central station conveniently situated with regard to a coal-field or a waterfall, and after transformation by means of electric generators into electric energy it may be transmitted to the locomotive and then by means of electric motors be transformed into mechanical energy at the axles to which the motors are applied. Every axle of an electric locomotive may thus be subjected to a torque, and the large weight which must be put on one pair of wheels in order to secure sufficient adhesion when all the driving is done from one axle may be distributed through as many pairs of wheels as desired. In fact, there need be no specially differentiated locomotive at all. Motors may be applied to every axle in the train, and their individual torques adjusted to values suitable to the weights naturally carried by the axles. Such an arrangement would be ideally perfect from the point of view of the permanent-way engineer, because it would then be possible to distribute the whole of the load uniformly between the wheels. This perfection of distribution is practically attained in present-day practice by the multiple control system of operating an electric train, where motors are applied to a selected number of axles in the train, all of them being under the perfect control of the driver.

The fundamental difference between the two methods is that while the mechanical energy developed by a steam engine is in the first case applied directly to the driving-axle of the locomotive, in the second case it is transformed into electrical energy, transmitted over relatively long distances, and retransformed into mechanical energy on the driving-axles of the train. In the first case all the driving is done on one or most two axles; sufficient tractive force being obtained by coupling these axles, which is necessary to others carrying heavy loads. In the second case every axle in the train may be made a driving-axle if desired, in which case the locomotive as a separate machine disappears. In the second case, however, there are all the losses due to transmission from the central station to the train to be considered, as well as the cost of the transmitting apparatus itself. Ultimately the question resolves itself into one of commercial practicability. For suburban traffic with a service at a few minutes’ interval and short distances between the stations electric traction has proved itself to be superior in many respects to the steam locomotive, but for main line traffic and long distance runs it has not yet been demonstrated that it is commercially feasible, though it is known to be practically possible. For the methods of electric traction see Traction; the remainder of the present article will be devoted to the steam locomotive.

§ 3. General Efficiency of Steam Locomotive.—One pound of good Welsh coal properly burned in the fire-box of a locomotive yields about 15,000 British thermal units of heat at a temperature high enough to enable from 50 to 80% to flow across the boiler-heating surface to the water, the rest escaping up the chimney with the flue gases. The heat produced in the fire-box is transferred from the furnace gas to the water carries heat to the cylinder, where 7 to 11% is transferred into mechanical energy, the remainder passing away up the chimney with the exhaust steam. The average result of many of these percentages, namely 0-65 X 0-09 X 0-06 = 0-06, may be used to investigate generally the working of a locomotive; the actual value could only be determined by experiment in any particular case. With this assumption, 0-06 is the heat energy of the coal which is utilized in the engine cylinders as mechanical work; that is to say, of the 15,000 B.Th.U. produced by the combustion of 1 lb of coal, 15,000 X 0-06 = 900 only are available for tractive purposes.

A series of experimental in 12,000 B.Th.U. per lb when burnt, whilst 15,000 is obtained from the best Welsh coals. Let E represent the pounds of coal burnt per hour in the fire-box of a locomotive, and let c be the calorific value in B.Th.U. per lb of the coal, then the mechanical energy available in four-pound per hour is approximately 0-06 X 778 X E, and this expressed in horse-power units gives

\[ \text{I.H.P.} = \frac{0-06 \times 778 \times E}{1,580,000} \]

A "perfect engine" receiving and rejecting steam at the same temperatures as the actual engine of the locomotive, would develop about twice this power, say 1,000 I.H.P. This figure represents the ideal but unattainable standard of performance. This question of the standard engine of comparison, and the engine efficiency is considered in § 11. The speed of the engine is then considered in § 11 below.

The indicated horse-power developed by a cylinder may always be ascertained from an indicator diagram and observations of the speed. Let \( p \) be the mean pressure in pounds per square inch, calculated as an average pressure obtained in a particular cylinder as the speed of the crank-shaft is \( n \) revolutions per second.

\[ \text{I.H.P.} = \frac{1}{2} \times 2 \pi \times I.H.P. = \pi \times \frac{550}{n} \times \frac{p}{144} \]

The indicated horse-power at the driving-axle, conveniently called the brake horse-power, is from 20 to 30% less than the indicated horse-power, and the ratio, B.H.P./I.H.P. = \( r \), is called the mechanical efficiency of the steam engine. The relation between the b.h.p. and the torque on the driving-axle is

\[ 550 \text{ B.H.P.} = T_w \]

It is usual with steam locomotives to regard the resistance \( R \) as including the frictional resistances between the cylinders and the driving-axle, so that the rate at which energy is expended in moving the train is expressed either by the product RV, or by the value of the indicated horse-power, the relation between them being

\[ 550 \text{ I.H.P.} = \text{RV} \]

or in terms of the torque

\[ 550 \text{ I.H.P.} \times \text{R} = \text{T}_{\text{w}} \]

The individual factors in the product RV may have any value consistent with equatoin (10) and with certain practical conditions, so that for a given value of the I.H.P. R must decrease if \( V \) increases. Thus if the maximum horse-power which a locomotive can develop is 1,000, the tractive resistance \( R \), at 60 m. per hour, is \( \frac{1,000 \times 550}{88} = 5500 \) lb. If, however, the speed is reduced to 15 m. per hour \( \frac{22 \text{ ft. per second}}{2} \) R increases to 25,000 lb. Thus an engine working at maximum power may be used to haul a relatively light load at a high speed or a heavy load at a slow speed.

§ 4. Analysis of Train Resistance.—Train resistance may be analysed into the following components:

(1) Journal friction and friction of engine machinery.
(2) Wind resistance.
(3) Resistance to changes in gradients, represented by \( R_1 \).
(4) Resistance due to miscellaneous causes.
(5) Resistance due to acceleration, represented by \( R_a \).
(6) Resistance due to curves.

The sum of all these components of resistance is at any instant equal to the resistance represented by \( R \). At a uniform speed on a level straight road 3, 5 and 6 are zero. The total resistance is conveniently divided into two parts: (1) the resistance due to the vehicles hauled by the engine, represented by \( R_1 \); (2) the resistance of the engine and tender represented by \( R_a \). In each of these two cases the resistance can of course be analysed into the six components set out in the above list.

§ 5. Vehicle Resistance and Draw-bar Pull.—The power of the engine is applied to the vehicles through the draw-bar, so that the draw-bar pull is a measure of the vehicle resistance. The draw-bar pull for given load is a function of the speed of the train, and numerous experiments have been made to find the relation connecting the pull with the speed under various conditions. The usual way of experimenting is to divide the train into two sections, one connected to the dynamometer car, the other to the locomotive and the train. This car is equipped with apparatus by means of which a continuous record of the draw-bar pull is obtained on a distance scale; time indications are also made on the diagram from which the speed at any instant can be deduced. The record thus obtained includes the resistances due to acceleration and to the gradient on which the train is moving. It is usual to subtract these resistances from the observed pull, so as to obtain the draw-bar pull reduced to that which it would be at uniform speed. All this divided by the weight of the vehicles hauled, in which must be included the weight of the dynamometer car, and the quotient gives the resistance per ton of load hauled at a certain uniform speed on a straight road and level ground. A series of experiments made by Aspinall on the Lancashire & Yorkshire railway to ascertain the resistance of trains of bogie passenger carriages of different lengths at varying speeds, and the results are recorded in a paper, “Train Resistance,” Proc. Inst. C.E. (1901), vol. 147. Aspinall’s results are expressed by the formula

\[ r_s = 2 \times 5 \times \frac{S^4}{50 \times 8.0 \times 0.0278} \]

where \( r_s \) is the resistance in pounds per ton, \( S \) is the speed in miles per hour, and \( L \) is the length of the train in feet measured over the...
RAILWAYS

LOCOMOTIVE POWER

Carriage bodies. The two following expressions are given in the Bulletin of the International Railway Congress (vol. xii. p. 1275), by Barbier, for some experiments made on the Northern railway of France with a train of 157 tons mean weight: they are valid between 37 and 77 m. per hour—

\[ r_e = \frac{3.58 + 0.65(1.61S + 50)}{1000} \]  
and \[ r_e = \frac{3.58 + 1.25S(1.61S + 10)}{1000} \] for 4-wheeled coaches, (13)

The Baldwin Locomotive Company give the formulae

\[ r_e = \frac{3.3 + 0.65S}{3} \]  
and \[ r_e = 1.68 + 0.224S \] for speeds from 47 to 77 m. per hour. (16)

All the above formulae refer to carriage stock. The resistance of goods wagons has not been so systematically investigated. In the paper above quoted Aspinall cites a case where the resistance of a train of empty wagons 1850 ft. long was 18.33 lb per ton at a speed of 26 m. per hour, and a train of full wagons 1045 ft. long gave only 9.12 lb per ton at a speed of 29 m. per hour. The resistance found from the above expressions includes the components 1, 2, and 4 of 4. The resistance caused by the wind is very variable, and in extreme cases may double the resistance found from the formulae. A side wind causes excessive flange friction on the leeward side of the train, and increases the tractive resistance therefore very considerably, even though its velocity be relatively moderate.

The curves corresponding to the above expressions are plotted in fig. 17, four values of \( L \) being taken for formula (12) corresponding to trains of 5, 10, 15 and 20 bogie carriages.

The resistance to starting is greater than the running resistance at moderate speeds. From Aspinall’s experiments it appears to be about 17 lb per ton, and this value is plotted on the diagram.

The resistance to motion round a curve has not been so systematically studied that any definite rule can be formulated applicable to all classes of rolling stock and all radii of curves. A general result could not be obtained, even from a large number of experiments, because the resistance round curves depends upon so many variable factors. In some cases the gauge is laid a little wider than the standard, and there are varying amounts of super-elevation of the outer rail; but the most formidable factor in the production of resistance is the gauge-iron, which is sometimes put in with the object of guiding the wheels which run on the inner rail of the curve on the inside of the flange.

§ 6. Engine Resistance.—From experiments made on the North-Eastern railway (see a paper by W. H. Smith on “Express Locomotive Engines,” Proc. Inst. Mech. Engrs., October 1898), it appeared that the engine resistance was about 3% of the total resistance, and in the train-resistance experiments on the Lancashire & Yorkshire railway quoted above the engine resistance was also about 35% of the total resistance, thus confirming the North-Eastern railway results. Barbier (loc. cit.) gives as the formula for the engine resistance

\[ r_e = \frac{8.58 + 3.245(1.61S + 30)}{1000} \]  
where S is the speed in miles per hour. This formula is valid between speeds of 37 and 77 m. per hour, and was obtained in connexion with the experiments previously quoted on the Northern railway of France with an engine and tender weighing about 83 tons. Barbier’s formula is plotted in fig. 17, together with a curve expressing generally the results of some early experiments on the Great Western railway results.

The forces on the Barrie curves beyond the above limits in fig. 17 gives values which must be regarded as only very approximate.

The speed, 30 m. per hour, is equal to 58.6 ft. per second; therefore the rate of working in foot-pounds per second is 3300 x 58.6, from which \( H.P. = (3300 x 58.6) / 550 = 354 \). This is the horse-power, therefore, which must be developed in the cylinders to maintain the train in motion at a speed of 30 m. per hour. If the engine is assumed to work on a level straight road with the values of the resistances assumed.

§ 8. Rate at which work is done against a gradient.—Gradients are measured either by stating the number of feet horizontally, \( G \) say, in which the vertical rise is 1 ft., or by the vertical rise in 100 ft. measured horizontally expressed as a percentage, or by the number of feet rising vertically in a mile. Thus a gradient of 1 in 200 is the same as a half per cent. grade or a rise of 26.4 ft. per mile. The difference between the horizontal distance and the distance measured along the road is so small that it is negligible in all practical calculations.

Hence if a train is travelling up the gradient at a speed of \( V \) ft. per second, the vertical rise per second is \( V/G \) ft. If \( W_1 \) is the weight of the train in pounds, the rate of working against the gradient expressed in horse-power units will be

\[ H.P. = W_1 V / 550 \] (18)

Assuming the data of the previous section, and in addition that the train is required to maintain a speed of 40 m. per hour up a gradient of 1 in 300, the extra horse-power required will be

\[ H.P. = 280 x 2240 x 58.6 / 3500 = 223 \] (19)

This must be added in addition to the horse-power calculated in the previous section, so that the total indicated horse-power which must be developed in the cylinders is now \( 354 + 223 = 577 \). If the train is running down a gradient this horse-power is the rate at which the energy of the train must be absorbed by the brake blocks, in order to maintain a constant speed. In the previous section, on the assumption that the train is running down a gradient of 1 in 300, the horse-power required to maintain the speed would be \( 354 - 223 = 211 \) (20).

§ 9. Rate at which work is done against acceleration.—If \( W \) is the weight of the train in pounds and \( a \) the acceleration in feet per second, the force required to produce the acceleration is

\[ f = W_1 a / g \] (21)

And if \( V \) is the average speed during the change of velocity implied by the uniform acceleration \( a \), the rate at which work is done by this force is

\[ fV = W_1 Va / g \] (22)

or in horse-power units

\[ H.P. = W_1 Va / 550g \] (23)

Assuming the data of § 7, suppose the train to change its speed from 40 to 44 m. per hour by the production of an average acceleration in feet per second measured by the fraction

\[ \text{Change of speed in feet per sec.} = \frac{60 - 07.5}{58.6} = \frac{10}{13}\ ]

Therefore the horse-power which must be developed in the cylinders to effect this change of speed is from (21)

\[ H.P. = 280 x 2240 x 113 x 58.6 / 550 x 13 = 237 \] (24)

The rate of working is negative when the train is retarded; for instance, if the train had changed its speed from 41 to 40 m. per hour in 13 seconds, the rate at which work would have to be absorbed by the brake blocks would represent 237 H.P. This is lost in heat produced by the friction between the brake blocks and the wheels, though in some systems of electric driving some of the energy stored in the train may be returned to the central station during retardation. The principal condition operating in the design of locomotives intended for local services with frequent stops is the degree of acceleration required, the aim of the designer being to produce an engine which shall be able to bring the train to its journey speed in the shortest time possible. For example, suppose it is required to start a train weighing 200 tons from rest and bring it to a speed of 30 m. per hour in 30 seconds. The weight of the engine may be assumed in advance to be 80 tons. The acceleration, \( a \), which may be supposed uniform, is \( 1.465 \). The average velocity is 15 m. per hour, which is equal to 22 ft. per second; therefore the tractive force for (required from (20), \( fV = 550g \), and this with \( f \) and \( V \) equal to the above values, 1130. To obtain the tractive force the weight on the coupled wheels must be added five times this amount—that is.

\[ (280 x 2240 x 113 x 58.6) / 32 = 58720 \] lb,

and the corresponding horse-power which must be developed in the cylinders is, from (20), \( fV/550 \), and this with \( f \) and \( V \) equal to the above values, 1140. To obtain the tractive force the weight on the coupled wheels must be about five times this amount—that is.
64 tons; and to obtain the horse-power the boiler will be one of the largest that can be built to the construction gauge. After acceleration to the journey speed of 30 m. per hour the horse-power required is reduced to about one-third of that required for acceleration alone.

§ 10. General expression for total rate of working.—Adding the various rates of working together,

\[
\frac{RV}{550} = \frac{(W_r + W_r)\gamma}{2240W} = \frac{2240W}{550\gamma} = \frac{2240W}{2220W} \quad (22)
\]

where \( W \) is weight of engine and tender in tons, \( W_r \) the weight of vehicles in tons, \( W_r \) the weight of engine and vehicle resistances taken from the curves fig. 17 at a speed corresponding to the average speed during the acceleration \( a \), \( G \) the gradient, \( g \) the acceleration due to gravity, and \( V \) the velocity of the train in feet per second. In this expression it is assumed that the acceleration is uniform, and this assumption is sufficiently accurate for any practical purpose to which the above formula would be applied in the ordinary working of a locomotive. If \( a \) is variable, then the formula must be applied in a series of steps, each step corresponding to a time interval over which the acceleration may be assumed uniform.

Dividing through by \( V \) and multiplying through by 550,

\[
R = \frac{W_r + W_r}{G} = \frac{2240W}{2220W} \quad (23)
\]

an expression giving the value of \( R \), the total active resistance. If the draw-bar pull is known to be \( R_r \), then applying the same principles to the vehicle along which the resistances are applied to the whole train,

\[
\text{total draw-bar pull} = \frac{W_r + W_r}{G} = \frac{2240W}{2220W} \quad (24)
\]

This expression may be used to find \( r \), when the total draw-bar pull is observed as well as the speed, the changes of speed and the gradient. The speed held to correspond with the resistance must be the mean speed during the change of speed. The best way of deducing \( r \) is to select positions of the dynamometer record where the speed is constant. Then a graph is made from all the above expressions. These expressions indicate what frequent changes in the power are required as the train pursues its journey up and down gradients, against wind resistance, journal friction and perhaps the resistance of a badly laid track; and show how the potential energy and kinetic energy of the train are continually changing: the first from a change in vertical position due to the gradients, the second from changes in speed. These considerations also indicate what a difficult matter it is to find the exact rate of working against the resistances, because of the difficulty of securing conditions which eliminate the effect both of the gradient and of acceleration.

§ 11. The Boiler.—Maximum Power.—The maximum power which can be developed by a locomotive depends upon the maximum rate of fuel combustion which can be maintained per square foot of grate. This maximum rate depends upon the kind of coal used, whether small, friable, bituminous or hard, upon the thickness of the fire, and upon the correct design and setting of the blast-pipe. A limit is reached to the rate of combustion when the draught becomes strong enough to carry the unburnt sparks through the tubes and chimney. This, besides reducing the efficiency of the furnace, introduces the danger of fire to crops and buildings near the line. The maximum rate of combustion may be as much as 150 lb. of coal per square foot of grate per hour, and in exceptional cases even a greater rate than this has been maintained. It is not economical to force the boiler to work at too high a rate, because it has been practically demonstrated that the boiler efficiency decreases after a certain point, as the rate of combustion increases. A few experimental results are set forth in Table XX, from which it will be seen that with a relatively low rate of combustion, a rate which denotes very light service, namely 28 lb. of coal per square foot of grate per hour, the efficiency of the boiler is 82 per cent, which is as good a result as can be obtained with the best class of stationary boiler or marine boiler even when using economizers.

The first group consists of experiments selected from the records of a large number made on the boilers of the locomotive belonging to the Purdue University, Indiana, U.S.A.

The second group consists of experiments made on a boiler belonging to the Great Eastern Railway Company. The first one of the group was made with the boiler fixed in the locomotive yard at Stratford, and the second remaining experiments of the group were made while the engine was working a train between London and March.

The third group consists of experiments selected from the records of a series of trials made on the London & South-Western railway with an express locomotive.

§ 12. Draught.—One pound of coal requires about 20 lb. of air for its proper combustion in the fire-box of a locomotive, though this quantity of air diminishes as the rate of combustion increases.

![Fig. 18.—Smoke-box. L. & N.W.R. four-coupled 6 ft. 6 in. passenger engine.](image-url)

The exhaust steam passing from the engine through the blast-pipe and the chimney produces a diminution of pressure, or
partial vacuum, fn the smoke-box roughly proportional to the weight of steam discharged per unit of time. The difference of pressure between the outside air and the smoke-box gases may be measured by the difference of the water levels in the limbs of a U tube, one limb being in communication with the smoke-box, the other with the atmosphere. The difference of levels varies from 1 to as much as 10 in. extreme cases. The draught corresponding to the smallest rate of combustion shown in Table XX. in Professor Goss's experiments, was 1.72 in. of water, and for the highest rate, namely 181, 7.48 in. of water. To get the best effect the area of the blast-nozzle must be properly proportioned to the size of the cylinders and be properly set with regard to the base of the chimney. The best proportions are found by trial in all cases.

Figs. 18 and 19 show two smoke-boxes typical of English practice. Fig. 18 is the smoke-box of the 6 ft. 6 in. six-coupled express passenger engine designed by G. Whale for the London & North-Western Railway Company in 1904, and fig. 19 shows the box of the four-coupled express passenger engine designed by J. Holden for the

The arrangements for arresting sparks in American practice and on the continent of Europe are somewhat elaborate. In English practice where a spark-arrester is put in it usually takes the form of a wire-netting dividing the smoke-box horizontally into two parts at a level just above the top row of tubes, or arranged to form a continuous connexion between the blast-pipe and the chimney.

Fig. 19 illustrates an arrangement designed by J. Holden. The heavy sparks are projected from the tubes in straight lines and are caught by the louvres L, L, and by them deflected downwards to the bottom of the smoke-box, where they collect in a heap in the space D round a tube which is essentially an ejector. At every blast a small quantity of steam is caught by the orifice O and led to the ejectors, one on each side, with the result that the ashes are blown out into the receptacles on each side of the engine, one of which is shown at E. The louvres I, I, are placed to shield the central region occupied by the blast-pipe.

As the indicated horse-power of the engine increases, the weight of steam discharged increases, and the smoke-box vacuum is increased, thereby causing more air to flow through the furnace and increasing the rate of combustion. Thus the demands for more steam is automatically responded to by the boiler. It is this close automatic interdependence of engine and boiler which makes the locomotive so extraordinarily well suited for the purpose of locomotive traction.

§ 13. The Steam Engine.—The steam engine of a locomotive has the general characteristics of a double-acting non-condensing engine (see Steam Engine). Distribution of steam is effected by a slide valve, sometimes fitted with a balancing device, and sometimes formed into a piston valve. All types of valves are with few exceptions operated by a link motion, generally of the Stephenson type, occasionally of the Allan type or the Gooch type, or with some form of radial gear as the Joy gear or the Walschaert gear, though the latter gear has characteristics which ally it with the link motions. The Stephenson link motion is used almost universally in England and America, but it has gradually been displaced by the Walschaert gear on the continent of Europe, and to some extent in England by the Joy gear. The general characteristics of the distribution effected by these gears are similar. Each of them, besides being a reversing gear, is an expansion gear both in forward and backward running. The lead is varied by the expression link motion, whilst in the Walschaert and the Joy gears it is constant. Illustrations of these gears are given in the article Steam Engine, and the complete distribution of steam for both forward and backward running is worked out for a typical example of each of them in Valves and Valve Gear Mechanisms by W. E. Dalby (London, 1906).

§ 14. Cylinder Dimensions.—Adhesion.—Tractive Force.—A locomotive must be designed to fulfil two conditions. First, it must be able to exert a tractive force sufficient to start the train under the worst conditions possible on the railway over which it is to operate—for instance, when the train is stopped by signal on a rising gradient where the track is curved and fitted with a guard-rail. Secondly, it must be able to maintain the train at a given speed against the total resistances of the level or up a gradient of given inclination. These conditions are to a certain extent mutually antagonistic, since an engine designed to satisfy either condition independently of the other would be a different engine from that designed to make the best compromise between them.

Equation (3), § 1 expresses the fundamental condition which must be satisfied when a locomotive is starting a train. The torque exerted on the driving-axle by the steam engine just at starting may be that due to the full boiler pressure acting in the cylinders, but usually the weight on the coupled wheels is hardly sufficient to enable advantage to be taken of the full boiler pressure, and it has to be throttled down by the regulator to prevent slipping. Sand, driven between the wheel and the rail by a steam jet, used just at starting, increases the adhesion beyond the normal value and enables a larger pressure to be exerted on the piston than would otherwise be possible. When the train is started and is moving slowly, the torque acting on the driving-axle may be estimated as that due to about 85% of the full boiler pressure acting in the cylinders. The torque
due to the two cylinders is variable to a greater or less extent, depending upon the degree of expansion in the cylinders and the speed. The form of the torque curve, or crank effect, as it is sometimes called, is discussed in the article STEAM ENGINE, and the torque curve corresponding to actual indicator diagrams taken from an express passenger engine travelling at a speed of 65 m. per hour is given in The Balancing of Engines by W. E. Dalby (London, 1906).

The plotting of the torque curve is laborious, but the average torque curve, which is all that is required for the purposes of this article, can be found quite simply by an approximate method. Let the maximum effective pressure in the cylinders, a, the area of the cylinder, and l, the stroke. Then the work done during one revolution of the crank is $\frac{2}{3}pl$ per cylinder. Assuming that the mean pressure in the other cylinder is also $p$, the total work done per revolution is $4pl$. If $T$ is the mean effective pressure on the crank-axle per revolution it is $2T$. Hence assuming the mechanical efficiency of the engine to be $\epsilon$, and substituting $\frac{2}{3}pl$ for the area $a$, we have

$$T = \frac{4pl}{\epsilon}$$

But from $\frac{1}{2} T = 4DF$; therefore

$$F = \frac{4pl}{\epsilon D} \quad (25)$$

In this expression $\epsilon$ is twice the average magnitude of the equal and opposite forces constituting the couple for one driving-wheel illustrated in fig. 16, one force of which acts to propel the train whilst the other is the varying tangential resistance between the wheel and the rail. This force $F$ must not exceed the value $\mu W$ or slipping will take place. Hence, if $\mu$ is the maximum value of the mean effective pressure corresponding to about 85% of the boiler pressure,

$$\mu W = \frac{4pl}{\epsilon D} \quad (26)$$

This is an expression giving a relation between the total weight on the coupled wheels, their diameters and the size of the cylinder. The maximum $F$ when $p$ and $\epsilon$ are put each equal to unity, is usually called the net admissible couple for the driving-wheels. The admissible couple for any given engine and driving-wheels must not in practice be uniform, a larger proportion of the weight falling on the driving-axle. The resisting forces the whole train be estimated at 16 lb per ton, this engine would be able to carry 163tons at the speed of 75 mph or 100 tons on a gradient of 1 in 75, both these figures including the weight of the engine and tender, which would be about 100 tons.

The engine can only exert a large tractive force so long as the mean effective pressure is maintained at 149 lb per square inch. This high mean pressure cannot be maintained for long, because as the speed increases the demand for steam per unit of time increases, so that cut-off must take place earlier and earlier in the stroke, the limiting speed of the engine being attained when the rate at which steam is supplied to the cylinders is adjusted by the cut-off to be equal to the maximum rate at which the boiler can produce steam, which depends upon the maximum rate at which coal can be burnt per square foot of grate per hour, the number of pounds of coal burnt per square foot of grate per hour, the calorific value of which is $C$. The number of horse-power is given by the expression

$$\text{I.H.P. maximum} = \frac{CA}{\sqrt{277x_7}} = 198000$$

where $A$ is the area of the grate in square feet, and $g$ is the combined efficiency of the engine and boiler. With the data of the previous example, and assuming in addition that the grate area is 24 sq. ft., that the rate of combustion is 150 lb of coal per square foot of grate per hour, the calorific value is 14,000, and finally that $\epsilon = 0.85$, the maximum indicated horse-power which the engine might be expected to develop would be $0.06X150X14000X24X787X198000 = 1190$, corresponding to a mean effective pressure in the cylinders of 149 lb per square inch.

Assuming that the train is required to run at a speed of 60 m. per hour, that is 88 ft. per second, the total resistance $R$, which the engine can overcome at this speed, is by equation (10)

$$R = (1950 \times 550) \times \frac{87}{4} = 7400 \text{ lb}.$$
it receives and rejects heat. Thus a standard of comparison for every individual engine may be obtained with which to compare its actual performance. The standard of comparison generally adopted for this purpose is obtained by calculating the efficiency of an engine working according to the Rankine cycle. That is to say, expansion is adiabatic and is continued down to the back pressure which in a non-condensing engine is 14.7 lb per square inch, since any back pressure above this amount is an imperfection which belongs to the actual engine. The back pressure is supposed to be uniform, and there is no compression.

Fig. 21 shows the pressure-volume diagram of the Rankine cycle for one pound of steam where the initial pressure is 175 lb per square inch by the gauge, equivalent to 190 lb per square inch absolute. In no case could an engine receiving steam at the temperature corresponding to this pressure and heating heat at 212° F. convert more heat into work than is represented by the area of this diagram. The area of this diagram may be measured, but it is usually more convenient to calculate the number of B.T.U. which the area represents from the following formula, which is expressed in terms of the absolute temperature $T_1$, of the steam at the steam-pipe, and the temperature $T_2=461 + 212 = 673$° absolute corresponding to the back pressure.

Maximum available work

$$W = \frac{U}{27} \left( T_1 - T_2 \right) \left( 1 - \frac{1}{T_1} \right) T_1 \log \frac{T_2}{T_1}$$

With the initial pressure of 190 lb per square inch absolute it will be found from a steam table that $T_1 = 838$° absolute. Using this and the temperature 673° in the expression, it will be found that $U = 185$ B.T.U. per pound of steam. If $h_1$ is the water heat at the lower temperature, $h_2$ the water heat at the higher temperature, and $L_1$ the latent heat at the higher temperature, the heat supply per pound of steam is equal to $h_1 + h_2 + L_1$, which, from the steam tables, with the values of the heat-supply given, is equal to 1013 B.T.U. per pound. The thermal efficiency is therefore

$$\frac{185}{1013} = 0.183,$$

That is to say, a perfect engine working between the limits of temperature assigned would convert only 18.3% of the total heat supply into work. This would be an ideal performance for an engine receiving steam at 190 lb initial pressure absolute, and rejecting steam at the back pressure assumed above, and could never be attained in practice. When the initial pressure is 100 lb per square inch by the gauge the thermal efficiency drops to about nearly 15% with the same back pressure. The way the thermal efficiency of the ideal engine increases with the pressure is exhibited in Fig. 22 by the curve AB. The curve was drawn by calculation to show the thermal efficiency from the above expression for various values of the initial temperature, keeping the final temperature constant at 673° and then plotting these efficiencies against the corresponding values of the temperature.

The actual thermal efficiencies observed in some of the cases cited in Table XXI, are plotted on the diagram, the reference numbers on which refer to the first column in the table. Thus the pressure in the steam-pipe being 167 lb per square inch. From the diagram it will be seen that the corresponding efficiency of the ideal engine is about 0.18. The efficiency ratio is therefore 0.11 to 0.18 or 0.61. That is to say, the engine actually utilized 61% of the energy which it was possible to utilize by means of a perfect engine working with the same temperature difference and the same temperature to the atmosphere. Lines representing efficiency ratios of 0.6, 0.5, and 0.4 are plotted on the diagram, so that the efficiency ratios corresponding to the various experiments plotted may be readily read off. The initial temperatures and the temperature of the steam taken in the steam-pipe must be the temperature of the steam taken in the steam-pipe. For further information regarding the standard engine of comparison see the article on Steam Engine and also the "Report of the Committee on the Thermal Efficiency of Steam Engines" Proc. Inst. C.E. (1868).

§ 16. Piston Speed.—The expression for the indicated horse-power may be written

$$P = \frac{c \cdot b \cdot a}{270}$$

where $b$ and $c$ are constants. (See W. E. Dalby, "The Economical Working of Locomotives" Proc. Inst. C.E., 1903-6, vol. 164.)

Substituting this value of $P$ in (27)

$$\text{I.H.P.} = \frac{c \cdot b \cdot a}{550}$$

the form of which indicates that there is a certain piston speed for which the I.H.P. is a maximum. In a particular case where the boiler pressure is 140 lb per square inch and the cut-off was approximately 20% of the stroke, the values $c = 55$ and $b = 0.91$ were deduced, from which it will be found that the value of the piston speed corresponding to the maximum horse-power is 89 ft. per minute. The data from which this result is deduced will be found in Professor Goss’s paper quoted above in Table XXI. The point is further illustrated by some curves published in the American Engineer (June 1901) by G. R. Henderson regarding the tests on engines made both on the Chicago & North-Western railway. Any modification of the design which will reduce the resistance to the flow of steam through the steam passages at high speeds will increase the piston speed for which the indicated horse-power is a maximum.

§ 17. Compound Locomotives.—The thermal efficiency of a steam-engine is in general increased by carrying out the expansion of the steam in two, three or even more stages in separate cylinders, notwithstanding the inevitable drop of pressure which must occur when the steam is transferred from one cylinder to the other in the process of expansion. Compound working permits of a greater range of expansion than is possible with a simple engine, and incidentally there is less range of pressure per cylinder, so that the pressures and temperatures per cylinder have not such a wide range of variation. In compound working the combined volumes of the low-pressure cylinders is a measure of the power of the engine, since this represents the final volume of the steam used per stroke. The volume of the high-pressure cylinder may be varied within wide limits for the same low-pressure volume; the proportions adopted should, however, be such that there is an absence of excessive drop between them as the steam is transferred from one to the other. Compound locomotives have been built by various designers, but opinion is still uncertain whether any commercial economy is obtained by their use. The varying load against which a locomotive works, and the fact that a locomotive is non-condensing, are factors which reduce the margin of possible economy within narrow limits. Coal-saving can be shown to the extent of about 14% in some cases, but the saving depends upon the kind of service on which the engine is employed. The first true compound locomotive was constructed in 1876 from designs by A. M. Mallet, at the Creusot works in Bayonne. The first true compound locomotive in England was constructed at Crewe works in 1878 by F. W. Webb. It was of the same type as Mallet’s engine, and was made by simply bushing one cylinder of an ordinary two-cylinder simple engine, the bushed cylinder being the high-pressure and the other cylinder the low-pressure cylinder. Webb evolved the type of three-cylinder compound with which his name is associated in 1882.
There were two high-pressure cylinders placed outside the frames and driving on a trailing wheel, and one low-pressure cylinder placed between the frames and driving on a wheel placed in front of the driving-wheel belonging to the high-pressure cylinders. The steam connexions were such that the two high-pressure cylinders were placed in parallel, both exhausting into the one low-pressure cylinder. The first engines of this class were provided with high-pressure cylinders, 11 in. diameter and 24 in. stroke, a low-pressure cylinder 26 in. diameter, 24 in. stroke, and driving-wheels 6 ft. 6 in. diameter; but subsequently these dimensions were varied. There were no coupling rods. A complete account of Webb's engines will be found in a paper, "The Compound Principle applied to Locomotives," by E. Worthington, Proc. Inst. C.E., 1889, vol. xcvi. Locomotives have to start with the full load on the engine, consequently an outstanding feature of every compound locomotive is the apparatus or mechanism added to enable the engine to start readily. Generally steam from the boiler is admitted direct to the low-pressure cylinder through a reducing valve, and valves and devices are used to prevent the steam so admitted acting as a back pressure on the high-pressure cylinder. In both compounds the driver opened communication from the high-pressure exhaust pipe to the blast-pipe, and at the same time opened a valve giving a supply of steam from the boiler direct to the low-pressure valve chest. T. W. Worsdell developed the design of the two-cylinder compound in England and built several, first for the Great Eastern railway and subsequently for the North-Eastern railway. The engines were built on the Worsdell and Von Borries plan, and were fitted with an ingenious starting-valve of an automatic character to overcome the difficulties of starting. Several compounds of a type introduced by W. M. Smith on the North-Eastern railway in 1898 have been built by the Midland railway. In these there are two low-pressure cylinders placed outside the frame, and one high-pressure cylinder placed between the frames. All cylinders drive on one crank-axle with three cranks at 120°. The driving-wheels are coupled to a pair of trailing wheels. A controlling valve enables the supply of steam to the low-pressure cylinders to be supplemented by boiler steam at a reduced pressure. For a description and illustrations of the details of the starting devices used in the Webb, Worsdell and Smith compounds, see an article, "The Development of the Compound Locomotive in England," by W. E. Dalby in the Engineering Magazine for September and October 1904. A famous type of compound locomotive developed on the continent of Europe is the four-cylinder De Glehn, some of which have been tried on the Great Western railway. There are two high-pressure cylinders placed outside the frame, and two low-pressure placed inside the frames. The low-pressure cylinders drive on the leading crank-axle with cranks at right angles, the high-pressure cylinders driving on the trailing wheels. The wheels are coupled, but the feature of the engine is that the coupling-rods act merely to keep the high-pressure and low-pressure engines in phase with one another, very little demand being made upon them to transmit force except when one of the wheels begins to slip. In this arrangement the whole of the adhesive weight of the engine is used in the best possible manner. An advantage of the engine is that the engine is practical divided between two axles. The engine can be worked as a four-cylinder simple at the will of the driver. S. M. Vauclain introduced a successful type of four-cylinder compound in America in 1889. A high- and low-pressure cylinders are cast together, and the piston-rods belonging to them are both coupled to one cross-head which is connected to the driving-wheels, these again being coupled to other wheels in the usual way. The distribution of steam to both cylinders is effected by one piston-valve operated by a link motion, so that there is considerable mechanical simplicity in the arrangement. Later Vauclain introduced the "balanced compound." In this engine the two piston-rods of one side are not coupled to a common cross-head, but drive on separate cracks at an angle of 180°, the pair of 180° cracks on each side being placed at right angles.

§ 18. The Balancing of Locomotives.—The unbalanced masses of a locomotive may be divided into two parts, namely, masses which revolve, as the crank-pins, the crank-cheeks, the coupling-rods, &c.; and masses which reciprocate, made up of the piston, piston-rod, cross-head and a certain proportion of the connecting-rod. The revolving masses are truly balanced by weight placed between the spokes of the wheels, or sometimes by prolonging the crank-webs and forming the prolongation into balance weights. It is also the custom to balance a proportion of the reciprocating masses by balance weights placed between the spokes of the wheels, and the actual balance weight seen in a driving-wheel is the resultant of the separate weights required for the balancing of the revolving parts and the reciprocating parts. The component of a balance weight which is necessary to balance the reciprocating masses introduces a vertical unbalanced force which appears as a variation of pressure between the wheel and the rail, technically called the hammer-blow, the magnitude of which increases as the square of the speed of the train. In consequence of this action there is usually followed of balancing only \( \frac{1}{3} \) of the reciprocating masses, thus keeping the hammer-blow within proper limits, and allowing \( \frac{1}{3} \) of the reciprocating masses to be unbalanced in the horizontal direction. It is not possible to do anything better with two-cylinder locomotives unless bogie weights are added, but with four-cylinder four-crank engines complete balance is possible both in the vertical and in the horizontal directions. When the four cranks are placed with two pairs at 180°, the pairs being at 90°, the forces are balanced without the introduction of a hammer-blow, but there remain large unbalanced couples, which if balanced by means of revolving weights in the wheels again reintroduce the hammer-blow, and if left unbalanced tend to make the engine oscillate in a horizontal plane at high speed. The principles by means of which the magnitude and position of balance weights are worked out are given in the article Mechanics (Applied Mechanics), and the whole subject of locomotive balancing is exhaustively treated with numerous examples in The Balancing of Engines by W. E. Dalby, London, 1906, § 10. Classification.—Locomotives may be classified primarily into "tender engines" and "tank engines," the water and fuel in the latter being carried on the engine proper, whilst in the former they are carried in a separate vehicle. A tender is generally mounted on six wheels, or in some cases on two bogies, and carries a larger supply of water and fuel than can be carried by tanks and the bunker of a tank engine. A tender, however, is so much dead-weight to be hauled, whilst the weight of the water and fuel in a tank engine contributes largely to the production of adhesion. A classification may also be made, according to the work for which engines are designed, into passenger engines, goods engines, and shunting or switching engines. A convenient way of describing any type of engine is by means of numerals indicating the number of wheels—

(i) in the group of wheels supporting the leading or chimney end, (ii) in the group of coupled wheels, and (iii) in the group supporting the trailing end of the engine. In the case where either the leading or trailing group of wheels is absent the number of the series of numbers used is reduced in the description. Thus 4-4-2 represents a bogie engine with four-coupled wheels and one pair of trailing wheels, the well-known Atlantic type; 4-2-2 represents a bogie engine with a single pair of driving-wheels and a pair of trailing wheels; 0-4-4 represents an engine with four-coupled wheels and a trailing bogie, and 4-4-0 an engine with four-coupled wheels and a leading bogie. A general description of the chief peculiarities of various kinds of locomotives is given in the following analysis of types—:

(1) "Single-driver" type, 4-2-2 or 2-2-2. Still used by several railways in Great Britain for express passenger service, but going out of favour; it is also found in France, and less often in Germany, Italy, and elsewhere in Europe. It is generally designed as a 4-2-2 engine, but some old types are still running with only three axles,
the 2â€”2. It is adapted for light, high-speed service, and noted for its simplicity, excellent riding qualities, low cost of maintenance, and high mechanical efficiency; but having limited adhesive weight it is unsuitable for starting and accelerating heavy trains.

(2) "Four-coupled" type, with leading bogie truck. For many years this was practically the only one used in America for all traffic, and it is often spoken of as the "American" type. In America it is the standard engine for passenger traffic, but for goods work on branch lines in Great Britain and France. It has been extensively introduced, both in Great Britain and the continent of Europe, for passenger traffic, and is now the most numerous and popular class. It is a safe, steady-running and trustworthy engine, with a service of "total adhesion" which is susceptible of a wide range of adaptability in power requirements.

(3) "Four-coupled" three-axle type, 2â€”4â€”0. Used to some extent in France and Germany and considerably in England for passenger traffic by modern railways. Engines of this class, with leading driving wheels and the leading axle fitted with Webb's radial axle-box, for many years did excellent work on the London & North-Western railroad. The famous engine "Charles Dickens" was of this class. Built in 1882, it had by the 12th of September 1891 performed miles in 9 years 219 days, and it completed two million miles on the 5th of August 1902, having by that date run 5312 trips with express trains between London and Manchester.

(4) "Four-coupled" three-axle type, with trailing axle, 0â€”4â€”2. Used on several English lines for fast passenger traffic, and also on many European railways. The advantages claimed for it are: short coupling-rods, large and unlimited fire-box carried by a trailing truck, and the result of good economy of well-proportioned engines. Its critics, however, accuse it of lack of stability, and assert that the use of large leading wheels as drivers results in rigidity and produces destructive strains on the machinery and permanent way.

(5) "Four-coupled" type, with a leading bogie truck and a trailing axle, 4â€”4â€”0. It is used to a limited extent both in England and on the continent of Europe, and is rapidly increasing in favour in the United States, where it originated and is known as the "American" type. It has many advantages for heavy goods service, namely, large and well-proportioned engine, practically unlimited grate area, fire-box of favourable proportions for firing, centrally placed cylinders, and, finally, a complete and ample riding frame. This arrangement is a four-coupled bogie type, with great steaming capacity and moderate axle loads. Occasionally a similar type is designed with the bogie under the fire-box and a single leading axle forward under the smoke-box, arrangement in favour for suburban tank engines. In still rarer cases both a leading and a trailing bogie have been fitted.

(6) "Six-coupled" bogie, or "Ten-wheel" type, 4â€”6â€”0. A powerful engine for heavy passenger and fast goods service. It is used to a limited extent both in Great Britain and on the continent of Europe, but is much more common in America. The design combines ample boiler capacity with large adhesive weight and moderate axle loads, but except on heavy gradients or for unusually large trains it is more economical in weight than the "American" type, and is more easily and economical handled by four-coupled locomotives of the eight-wheel or Atlantic types.

(7) "Six-coupled" total-adhesion type (all the weight carried on the leading truck). This is the "American" engine of Great Britain and the continent of Europe. In America the type is used only for shunting. It is a simple design of moderate boiler power.

(8) "Six-coupled" type, with a leading axle, 2â€”6â€”0. This is of growing popularity and is known as "Consolidation." It is used largely in America for goods traffic. In Europe it is in considerable favour for goods and passenger traffic on heavy gradients. The type is, however, less in favour than either the ten-wheel or the eight-wheel "Consolidation" as already defined.

(9) "Eight-coupled" total-adhesion type, 0â€”8â€”0; now found on a good many English railways, and common on the continent of Europe for heavy slow goods traffic. In America it is comparatively infrequent in high-tonnage type, but is extensively used for goods traffic.

(10) "Eight-coupled" type, with a leading axle, 2â€”8â€”0. This originated in America, where it is termed the "Consolidation." In the United States it is the standard heavy slow-speed freight engine, and has been built in enormous size and weight. The type has been introduced in Europe, especially in Germany, with advantages of a partial-adhesion type in increased stability and a larger boiler are becoming appreciated. Occasionally the American eight-coupled type has a bogie instead of a single leading axle (4â€”8â€”0); then termed a "4â€”8â€”0" or "4â€”8â€”0-0." The "Decapod" is used to a limited extent for mountain grade goods traffic, and has the combination of a "Consolidation" and eight-coupled type of lighter axle loads for a given tractive capacity.

In addition to the foregoing list, various special locomotive types have been developed for suburban service, where high rates of acceleration and frequent stops are required. These are generally tank engines, carrying their fuel and water on the engine proper.

Their boilers are of relatively large proportions for the train weight and average speed, and the driving wheels of small diameter, a large proportion of their total weight being "adhesive." Other special types are in limited use for "rack-railways," and operate either by engagement of gearing on the locomotive into a rack between the track rails, or by a combination of this and rail adhesion.

§ 20. Current Developments.—The demand of the present day is for engines of larger power both for passenger and goods service, and the problem is to design such engines within the limitations fixed by the 4 ft. 8¾ in. gauge and the dimensions of the existing tunnels, arches, and other permanent works. The American engineer is more fortunately situated than his English brother with regard to the possibility of a solution, as will be seen from the comparative diagrams of construction, Figs. 23, 24, 25, 26. Fig. 23 shows the construction gauge for the London & North-Western railway, fig. 24 that for the Great Western, fig. 25 that for the Great Eastern railway, whilst fig. 26 gives a general idea of the American gauge in a particular case, generally typical, however, of the American limits. In consequence of this increasing demand for power, higher boiler pressures are being used, in some cases 225 lb per sq. in. for a simple two-cylinder engine, and cylinder volume is slightly increased with the necessary accompaniment of heavier loads on the coupled wheels to give the necessary adhesion. Both load and speed have increased so much in connexion with passenger trains that it is necessary to divide the weight required for adhesion between three-coupled axles, and the type of engine gradually coming into use in England for heavy express traffic is a six-coupled engine with a leading bogie, with wheels which would have been considered small a few years ago for the speed at which the engine runs. The same remarks apply to goods engines. There is a great increase in cylinder power, boiler pressure and weight, and in consequence in the number of coupled axles. Not only are the load and speed increasing, but the distances run without a stop are increasing also, and to avoid increasing the size of the tenders, water-troughs, first instituted by J. Ramsbottom on the London & North-Western railway in 1859, have been laid in the tracks of the leading main lines of Great Britain. For local services where stoppages are frequent the demand is for engines capable of quickly

1 At the beginning of 1908 the Great Western's loading gauge on its main lines was widened to 9 ft. 8 in. from a height of 5 ft. above rail level.
The rolling stock of a railway comprises those vehicles by means of which it effects the transportation of persons and things over its lines. It may be divided into two classes, according as it is intended for passenger or for goods traffic.

Passenger Train Stock.—In the United Kingdom, as in Europe generally, the vehicles used on passenger trains include first-class carriages, second-class carriages, third-class carriages, composite carriages containing compartments for two or more classes of passengers, dining or restaurant carriages, sleeping

accelerating the train to the journey speed. The nature of this problem is illustrated by the numerical example in § 9. When the service is frequent enough to give a good power factor continuously, the steam locomotive cannot compete with the electric motor for the purpose of quick acceleration, because the motors applied to the axles of a train may for a short time absorb power from the central station to an extent far in excess of anything which a locomotive boiler can supply.

With regard to the working of the locomotive, J. Holden developed the use of liquid fuel on the Great Eastern railway to a point beyond the experimental stage, and used it instead of coal with the engines running the heavy express traffic of the line, its continued use depending mainly upon the relative market price of coal and oil. Compound locomotives have been tried, as stated in § 17, but the tendency in England is to revert to the simple engine for all classes of work, though on the continent of Europe and in America the compound locomotive is largely adopted, and is doing excellent work. A current development is the application of superheaters to locomotives, and the results obtained with them are exceedingly promising.

The leading dimensions of a few locomotives typical of English, American and European practice are given in Table XXII.

(1. E. D.)

ROLLING STOCK
carriages, mail carriages or travelling post offices, luggage brake vans, horse-boxes and carriage-trucks. Passenger carriages were originally modelled on the stage-coaches which they superseded, and they are often still referred to as "coaching stock." Early examples had bodies about 15 ft. long, 6½ ft. wide and 4½ ft. high; they weighed 3 or 4 tons, and were divided into three compartments holding six persons each, or eighteen in all.

The distinction into classes was made almost as soon as the railways began to carry passengers. Those who paid the highest fares (2½d. or 3d. a mile) were provided with covered vehicles, on the roofs of which their luggage was carried, and from the circumstance that they could book seats in advance came the term "booking office," still commonly applied to the office where tickets are issued. Those who travelled at the cheaper rates had at the beginning to be content with open carriages having little or no protection from the weather. Gradually, however, the accommodation improved, and by the middle of the 19th century second-class passengers had begun to enjoy "good glass windows and cushions on the seat," the fares they paid being about 2d. a mile. But though by an act of 1844 the railways were obliged to run at least one train a day over their lines, by which the fares did not exceed the Parliamentary rate of 1d. a mile, third-class passengers paying 1d. 6d. or 2d. a mile, there was considerable leniency in their comfort, and were excluded from the fast trains till 1872, when the Midland railway admitted them to all its trains. Three years later that railway did away with second-class compartments and improved the third class to their level. This action had the effect, through the necessities of competition, of causing travellers in the cheaper classes to be better treated on other railways, and the condition of the third-class passenger was still further improved when Parliament, by the Cheap Trains Act of 1883, required the railways to provide "due and sufficient" train accommodation at fares not exceeding 1d. a mile. In the United Kingdom it is now possible to travel by every train, with very few exceptions, and in many cases to have the use of restaurant cars, for 1d. a mile or less, and the money obtained from third-class travellers forms by far the most important item in the revenue from passenger traffic. Since the Midland railway's action in 1872 several other English companies have abandoned second-class carriages either completely or in part, and in Scotland they are entirely unknown.

On the continent of Europe there are occasionally four classes, but though the local fares are often appreciably lower than in Great Britain, only first and second class, sometimes only first class, passengers are admitted to the fastest trains, for which in addition a considerable extra fare is often required. In Hungary and Russia a zone-tariff system is in operation, whereby the charge per mile decreases progressively with the length of the journey, the traveller paying according to the number of zones he has passed through and not simply according to the distance traversed. In the United States there is in most cases nominally only one class, denominated first class, and the average fare obtained by the railways is about 1d. per mile per passenger. But the extra charges levied for the use of parlour, sleeping and other special cars, of which some of the best trains are exclusively composed, in practice constitute a differentiation of class, besides making the real cost of travelling higher than the figures just given.

In America and other countries where distances are great and passengers have to spend several days continuously in a train sleeping and restaurant cars are almost a necessity, and accordingly are to be found on most important through trains. Such cars in the United States are largely owned, not by the railway companies over whose lines they run, but by the Pullman Car Company, which receives the extra fees paid by passengers for their use. Similarly in Europe they are often the property of the International Sleeping Car Company (Compagnie Internationale des Wagons-Lits), and the supplementary fares required from those who travel in them add materially to the cost of a journey. In the United Kingdom, where the distances are comparatively small, sleeping and dining cars must be regarded rather as luxuries; still even so, they are to be met with very frequently. The first dining car in England was run experimentally by the Great Northern railway between London and Leeds in 1879, and now such vehicles form a common feature on express trains, being available for all classes of passengers without extra charge beyond the amount payable for food. The introduction of corridor carriages, enabling passengers to walk right through the trains, greatly increased their usefulness. The first English sleeping cars made their appearance in 1873, but they were very inferior to the vehicles now employed. In the most approved type at the present time a passage runs along one side of the car, and off it open a number of transverse compartments or berths resembling ships' cabins, mostly for one person only, and each having a lavatory of its own with cold, and sometimes hot, water laid on. A charge of 7s. 6d. or 10s., according to distance, is made for each bed, in addition to the first-class fare. In the United States the standard sleeping car has a central alley, and along the sides are two tiers of berths, arranged lengthwise with the car and screened off from the alley by curtains. To some extent cars divided into separate compartments are also in use in that country. On the continent of Europe the typical sleeping car has transverse compartments with two or three berths each, placed side by side, and divided from the central aisle by a cupboard or washstand. The first railway carriages in England had four wheels with two axles, and this construction is still largely employed, especially for short-distance trains. Later, when increased length became desirable, six wheels with three axles came into use; vehicles of this kind were made about 30 ft. long, and contained four compartments for first-class passengers or five for second or third class, carrying in the latter case fifty persons. Their weight was in the neighbourhood of 10 tons. In both the four-wheeled and the six-wheeled types the axles were free to rise and fall on springs through a limited range, but not to turn with respect to the body of the carriage, though the middle axle of the six-wheeled coach was allowed a certain amount of lateral play. Thus the length of the body was limited, for to increase it an increase in the length of the rigid wheel base, which was incompatible with smooth and safe running on curves. (On the continent of Europe, however, six-wheeled vehicles are to be found much longer than those employed in Great Britain.) This difficulty is avoided by providing the vehicles with four axles, the case of the largest and heaviest, in pairs, or bogies (or threes) at each end in a bogie or swivel truck, which being pivoted can move relatively to the body and adapt itself to the curvature of the line. This construction was introduced into England from America about 1874, and has since been extensively adopted, being now indeed standard for main line stock. It soon led to an increase in the length of the vehicles; thus in 1885 the Midland railway had four-wheeled bogie third-class carriages with bodies 43 ft. long, holding seventy persons in seven compartments and weighing nearly 18 tons, and six-wheeled bogie composite carriages, 54 ft. long and weighing 23 tons, which included 3 first-class and 4 third-class compartments, with a cupboard for luggage, and held 58 passengers. The next advance, introduced on the Great Western railway in 1892, was the adoption of corridor carriages having a passage along one side, off which the compartments open, and connected to each other by vestibules, so that it is possible to pass from one end of the train to the other. This arrangement involves a further increase of length and weight. For instance, four-wheeled bogie third-class corridor carriages employed on the Midland railway at the beginning of the 20th century weighed nearly 25 tons, and had bodies measuring 50 ft.; yet they held only 36 passengers, because not only had the number of compartments been reduced to six, as compared with seven in the somewhat shorter carriage of 1885, by the introduction of a lavatory at each end, but each compartment held only 6 persons, instead of 10, owing to the narrowing of its width by the corridor.
It will be seen from these particulars—which are typical of what has happened not only on other British railways, but also on those of other countries—that much more space has to be provided and more weight hauled for each passenger than was formerly the case. Thus, on the Midland railway in 1885, each third-class passenger, supposing the carriage to have its full complement, was allowed 0.62 ft. of lineal length, and his proportion of the total weight was 5.7 cwt. Less than 20 years later the lineal length allowed each had increased to nearly 1.2 ft., and the weight to nearly 14 cwt. Passengers in sleeping cars appropriate still more space and weight; in Great Britain some of these cars, though 40 tons in weight and over 65 ft. in length, accommodate only 11 sleepers, each of whom thus occupies nearly 6 ft. of the length and requires over 31 tons of dead weight to be hauled.

In America the long open double-bogie passenger cars, as originally introduced by Ross Winans on the Baltimore & Ohio railway, are universally in use. They are distinguished essentially from the British type of carriage by having in the centre of the body a longitudinal passage, about 2 ft. wide, which runs their whole length, and each car having communication with those on either side of it, the conductor, and also vendors of books, papers and cigars, are enabled to pass right through the train. The cars are entered by steps at each end, and are provided with lavatories and a supply of iced water. The length is ordinarily about 50 ft., but sometimes 80 or 90 ft. The seats, holding two persons, are placed transversely on each side of the central passage, and have reversible backs, so that passengers can always sit facing the direction in which the train is travelling. Cars of this saloon type have been introduced into England for use on railways which have adopted electric traction, but owing to the narrower loading gauge of British railways it is not usually possible to seat four persons across the width of the car for its whole length, and at the ends of the cars have to be placed along the sides of the vehicle. A considerable amount of standing room is then available, and those who have to occupy it have been nicknamed "strap-hangers," from the fact that they steady themselves against the motion of the train by the aid of leather straps fixed from the roof for that purpose. Cars built almost entirely of steel, in which the proportion of wood is reduced to a minimum, are used on some electric railways, in order to diminish danger from fire, and the same mode of construction is also being adopted for the rolling stock of steam railways.

End doors opening on end platforms have always been characteristic of American passenger equipment. Their use secures a continuous passage-way through the train, but is attended with some discomfort and risk when the train is in motion. The opening of the doors was apt to cause a disagreeable draught through the car in cold weather, and passengers occasionally fell from the open platform, or were blown from it, when the train was moving. To remedy these defects vestibules were introduced, to enclose the platform with a housing so arranged as to be continuous when the cars are made up into trains, and fitted with side doors for ingress and egress when the trains are standing. A second advantage of the vestibule developed in use, for it was found that the lateral swaying of the cars was diminished by the friction between the vestibule frames. The fundamental American vestibule patent, issued to H. H. Sessions of Chicago in November 1887, covered a housing in combination with a vertical metallic plate frame of the general contour of the central passage-way, which projected slightly beyond the line of the couplings and was held out by horizontal springs top and bottom, being connected with the platform housing by flexible connexions at the top and sides and by sliding plates below. A common form is illustrated in fig. 27. Subsequent improvements on the Sessions patent have resulted in a modified form of vestibule in which the housing is made the full width of the platform, though the contact plate and springs and the flexible connexions remain the same as before. The application of vestibules is practically limited to trains making long journeys, as it is an obstruction to the free ingress and egress of passengers on local trains that make frequent stops.

In the United States the danger of the stoves that used to be employed for heating the interiors of the cars has been realized, and now the most common method is by steam taken from the locomotive boiler and circulated through the train in a line of piping, rendered continuous between the cars by flexible coupling-hose. The same method is finding increased favour in Great Britain, to the supersession of the old hot-water footwarmers. These in their simplest form are cans filled with water, which is heated by immersing them in a vessel containing boiling water. In some cases, however, they are filled with fused acetate of soda; this salt is solid when cold, but when the can containing it is heated by immersion in hot water it liquefies, and in the process absorbs heat which is given out again on the change of state back to solid. Such cans remain warm longer than those containing only hot water. On electric railways the trains are heated by electric heaters. As to lighting, the oil lamp has been largely displaced by gas and electricity. The former is often a rich oil-gas, stored in steel reservoirs under the coaches at a pressure of six or seven atmospheres, and passed through a reducing valve to the burners; these used to be of the ordinary fish-tail type, but inverted incandescent mantles are coming into increasing use. Gas has the disadvantage that in case of a collision its inflammability may assist any fire that may be started. Electric light is free from this drawback. The current required for it is generated by dynamos driven from the axles of the coaches. With "set" or "block" trains, that is, trains having their vehicles permanently coupled up, one dynamo may serve for the whole train, but usually a dynamo is provided for each coach, which is then an
independent unit complete in itself. It is necessary that the voltage of the current shall be constant whatever be the increase of the speed of the train, and therefore of the dynamo. In most of the systems that have been proposed this result is attained by electrical regulation; in one, however, a mechanical method is adopted, the dynamo being so hung that it allows the driving belt to slip when the speed of the axle exceeds a certain limit, the armature thus being rotated at an approximately constant speed. In all the systems accumulators are required to maintain the light when the train is at rest or is moving too slowly to generate current.

In all countries passenger trains must vary in weight according to the different services they have to perform; suburban trains, for example, meant to hold as many passengers as possible, and travelling at low speeds, do not weigh so much as long-distance expresses, which include dining and sleeping cars, and on which, from considerations of comfort, more space must be allowed each occupant. The speed at which the journey has to be completed is obviously another important factor, though the increased power of modern locomotives permits trains to be heavier and at the same time to run as fast, and often faster, than was formerly possible, and in consequence the general tendency is towards increased weight as well as increased speed. An ordinary slow suburban train may weigh about 100 tons exclusive of the engine, and may be timed at an inclusive speed, from the beginning to the end of its journey, as low as 12 or 15 m. an hour; while usually the fastest expresses maintain average speeds of 15 to 18 m. an hour, and made up of the heaviest and strongest rolling stock, do not much exceed 300 tons in any country, and are often less. The inclusive speed over a long journey is of course a different thing from the average running speed, on account of the time consumed in intermediate stops; the fewer the stops the more easily is the inclusive speed increased;—hence the advantage of the non-stop runs of 150 and 200 m. or more which are now performed by several railways in Great Britain, and on which average speeds of 55 or 55 m. per hour are attained between stopping-places. Over shorter distances still more rapid running is occasionally arranged, and in Great Britain, France and the United States there are instances of trains scheduled to maintain an average speed of 60 m. an hour or more between stops. Still higher speeds, up to 75 or even 80 m. an hour, are reached, and sustained for shorter or longer distances every day by express trains whose average speed between any two stopping-places is very much less. But isolated examples of high speeds do not give the traveller much information as to the train service at his disposal, for on the whole he is better off with a large number of trains all maintaining a good average of speed than with a service mostly consisting of poor trains, but leavened with one or two exceptionally fast ones. If both the number and the speed of the trains be taken into account, Great Britain is generally admitted still to remain well ahead of any other country.

**Goods Trains.**—The vehicles used for the transportation of goods are known as goods wagons or trucks in Great Britain, and as freight cars in America. The principal types to be found in the United Kingdom and on the continent of Europe are open wagons (the lading often protected from the weather by tarpaulin sheets), mineral wagons, covered or box wagons for cotton, grain, &c., sheep and cattle trucks, &c. The principal types of American freight cars are box cars, gondola cars, coal cars, stock cars, tank cars and refrigerator cars, with, as in other countries, various special cars for special purposes. Most of these terms explain themselves. The gondola or flat car corresponds to the European open wagon and is used to carry goods not liable to be injured by the weather; but in the United States the practice of covering the load with tarpaulins is unknown, and therefore the proportion of box cars is much greater than in Europe. The long hauls in the United States make it specially important that the cars should carry a load in both directions, and so box cars which have carried grain or merchandise one way are filled with wool, coal, coke, ore, timber and other coarse articles for the return journey. On this account it is common to put small end doors in American box cars, through which timber and rails may be loaded.

The fundamental difference between American freight cars and the goods wagons of Europe and other lands is in carrying capacity. In Great Britain the mineral trucks can ordinarily hold from 8 to 10 tons (long tons, 2240 lb), and the goods trucks rather less, though there are wagons in use holding 12 or 15 tons, and the specifications agreed to by the railway companies associated in the Railway Clearing House permit private wagon owners (who own about 45% of the wagon stock run on the railways of the United Kingdom) to build also wagons holding 20, 30, 40 and 50 tons. On the continent of Europe the average carrying capacity is rather higher; though wagons of less than 10 tons capacity are in use, many of those originally rated at 10 tons have been rebuilt to hold 15, and the tendency is towards wagons of 15-20 tons as a standard, with others for special purposes holding 40 or 45 tons.

The majority of the wagons referred to above are comparatively short, and carried on four wheels, and are often made of wood. American cars, on the other hand, have long bodies mounted on two swivelling bogie-trucks of four wheels each, and are commonly constructed of steel. About 1875 their average capacity differed little from that of British wagons of the present day, but by 1885 it had grown to 20 or 22 short tons (2000 lb) and now it is probably at least three times that of European wagons. For years the standard freight cars have held 60,000 lb and now many carry 80,000 lb or 100,000 lb; a few coal cars have even been built to contain 200,000 lb. This high carrying capacity has worked in several ways to reduce the cost of transportation. An ordinary British 10-ton wagon often weighs about 6 tons empty, and rarely much less than 5 tons; that is, the ratio of its possible paying load to its tare weight is at the best about 2 to 1. But an American car with a capacity of 100,000 lb may weigh only 40,000 lb, and thus the ratio of its capacity to its tare weight is only about 5 to 2. Hence less dead weight has to be hauled for each ton of paying load. In addition the increased size of the American freight car has diminished the interest on the first cost and the expenses of maintenance relatively to the work done; it has diminished to some extent the amount of track and yard room required to perform a unit of work; it has diminished journal and rolling friction relatively to the tons hauled, since those elements of train resistance grow relatively less as the load per wheel rises; and finally, it has tended to reduce the labour costs as the train loads have become greater, because no more men are required to handle a heavy train than a light one.

It is sometimes argued that if these things are true for one country they must be true for another, and that in Great Britain, for example, the use of more capacious cars would bring down the cost of carriage. It may be pointed out, however, that the social and geographical conditions are different in the United Kingdom and the United States, and in each country the methods of carrying goods and passengers have developed in accordance with the requirements of those conditions. In the United States the population is dense, large towns are numerous and close to one another, the greatest distances to be travelled are short, and relatively little of the freight to be carried is merchandise and manufactured material consigned in small quantities. In the other country precisely the opposite conditions exist. Under the first set of conditions quickness and flexibility of service are relatively more important than under the second set. Goods therefore are collected and despatched promptly, and, to secure rapid transit, are packed in numerous wagons, each of which goes right through to its destination, with the consequence that, so far as general merchandise is concerned, the weight carried in each is a quarter or less of its capacity. But if full loads cannot be arranged for small wagons, there is obviously no economy in introducing larger ones. On the other hand, where, as in America, the great
RAILWAYS

ROLLING STOCK]

volume of freight is raw material and crude food-stuffs, and
the distances are great, a low charge per unit of transportation
is more important than any consideration such as quickness
of delivery; therefore full car-loads of freight are massed
into enormous trains, which run unbroken for distances of
perhaps 1000 m. to a seaport or distributing centre.
The weight and speed of goods trains vary enormously
according to local conditions, but the following figures, which
refer to traffic on the London & North-Western

as representative of good English practice.
Coal
trains, excluding the engine, weigh up to 800 or 900 tons,
and travel at from 18 to 22 m. an hour; ordinary goods or
merchandise trains, weighing 430 tons, travel at from 25 to 30 m.
an hour; and quick merchandise trains with limited loads of
300 tons make 35 to 40 m. an hour. In the United States
mineral and grain trains, running at perhaps 12 m. an hour, may
weigh up to about 4000 tons, and loads of 2000 tons are common.
Merchandise trains run faster and carry less. Their speed must
obviously depend greatly on topographical conditions. In the
great continental basin there are long lines with easy gradients
and curves, while in the Allegheny and Rocky Mountains the
gradients are

stiff,

Couplers.
The means by which vehicles are joined together
two kinds automatic and non-automatic,
the difference between them being that with the former the
impact of two vehicles one on the other is sufficient to couple
them without any human intervention such as is required with
the latter. The common form of non-automatic coupler, used
in Great Britain for goods wagons, consists of a chain and hook;
the chain hangs loosely from a slot in the draw-bar, which
terminates in a hook, and coupling is effected by slipping the
chain of one vehicle over the hook of the next. For this operation, or its reverse, a man has to go in between the wagons,
unless, as in Great Britain, he is provided with a coupling-stick
that is, a pole having a peculiarly shaped hook at one end by
which the chain can be caught and thrown on or off the drawbar hook. This coupling gear is placed centrally between a
pair of buffers; formerly these were often left " dead " that is,
consisted of solid prolongations of the frame of the vehicle,
but now they are made to work against springs which take up
the shocks that occur when the wagons are thrown violently
against one another in shunting. In British practice the chains
consist of three links, and are of such a length that when fully
extended there is a space of a few inches between opposing
buffers; this slack facilitates the starting of a heavy train,
since the engine is able to start the wagons one by one and the
weight of the train is not thrown on it all at once. For passenger
trains and occasionally for fast goods trains screw couplings are
substituted for the simple chains.
In these the central bar
which connects the two end links has screw threads cut upon it,
and by means of a lever can be turned so as either to shorten
the coupling and bring the vehicles together till their buffers
are firmly pressed together, or to lengthen it to permit the end
into trains are of

link to be lifted off the hook.

Another form of coupler, which used to be universal in the
United States, though it has now been almost entirely superseded by the automatic coupler, was the " link and pin," which
differed fundamentally from the couplers commonly used in
Europe, in the fact that it was a buffer as well as a coupler, no
side buffers being fitted. In it the draw-bar, connected through
a spring to the frame of the car, had at its outboard end a socket
into which one end of a solid link was inserted and secured by a
pin.
The essential change from the link and pin to the automatic coupler is in the outboard end or head of the draw-bar.
The socket that received the link is replaced by a hook, shown at
A in fig. 28, which is usually called the knuckle. This hook

855

swings on the pivot B, and has an

arm which extends backwards,

practically at right angles with the working face of the hook,

Fig. 28.

—Automatic

Coupling for Freight Cars (U.S.A.).

and engages with the locking-pin C.
This locking-pin is lifted by a suitable lever which extends to
one or both sides of the car; lifting it releases the knuckle,
which is then free to swing open, disconnecting the two cars.
The knuckle stands open until the coupling is pushed against
another coupling, when the two hooks turn on their pivots to
the position shown in fig. 28, and, the locking-pin dropping
into place, the couplers are made fast.
This arrangement is
only partly automatic, since it often happens that when two cars
are brought together to couple the knuckles are closed and must
be opened by hand. There are various contrivances by which
this may be done by a man standing clear of the cars, but often
he must go in between their ends to reach the knuckle.
This form of automatic coupler has now gained practically
universal acceptance in the United States.
To effect this
result required many years of discussion and experiment. The
Master Car Builders' Association, a great body of mechanical
officers organized especially to being about improvement and
uniformity in details of construction and operation, expressed
its sense of the importance of " self-coupling " so far back as
in a cavity in the head,

1874, but no device of the kind that could be considered useful
had then been invented. At that time a member of the Association referred to the disappearance of automatic couplers which
had been introduced thirty or forty years before. This body
pursued the subject with more or less diligence, and in 1884 laid

down

the principle that the automatic coupler should be one
acting in a vertical plane that is, the engaging faces should be
free to move up and down within a considerable range, in order
to provide for the differences in the height of cars. By the fixing

—

this principle the task of the inventor was considerably
In 1887 a committee reported that the coupler
question was the " knottiest mechanical problem that had ever
been presented to the railroad," and over 4000 attempted
solutions were on record in the United States Patent Office.
The committee had not found one that did not possess grave
disadvantages, but concluded that the " principle of contact of
the surfaces of vertical surfaces embodied in the Janney coupler
afforded the best connexion for cars on curves and tangents ";
and in 1887 the Association recommended the adoption of a
coupler of the Janney type, which, as developed later, is shown in
fig. 28.
The method of constructing the working faces of this
coupler is shown in fig. 29. The principle was patented, but
the company owning the patent undertook to permit its free use
by railway companies which were members of the Master Car
Builders' Association, and thus threw open the underlying
principle to competition. From that time the numerous patents
have had reference merely to details. Many different couplers
of the Janney type are patented and made by different firms,
but the tendency is to equip new cars with one of only four or
five standard makes.
The adoption of automatic couplers was
stimulated in some degree by laws enacted by the various states
and by the United States; and the Safety Appliance Act passed
by Congress in 1893 made it unlawful for railways to permit to
be hauled on their lines after the 1st of January 1898 any car
used for interstate commerce that was not equipped with
couplers which coupled automatically by impact, and which
could be uncoupled without the necessity for men going in
between the ends of the cars. The limit was extended to the
1st of August 1900 by the Interstate Commerce Commission,
which was given discretion in the matter.

of

simplified.


RAILWAYS

Automatic couplers resembling the Janney are adopted in a few special cases in Great Britain and other European countries.

The sides of the square are 6 in., and the centres AA are taken at 2 in. from the top and bottom of the square. The circles A'A', which are struck with 2-in. radius, define the first portion of the knuckle. The inner circle B has a radius of 1½ in. From its intersection with A'A' arcs are struck cutting B in two points. These intersections determine the centres of the semi-circles CC which form the ends of the respective knuckles. These semicircles and the circles A'A' are joined by tangents and short arcs struck from the centre of the figure. The great majority of couplings remain non-automatic. It may be pointed out that the general employment of side buffers in Europe greatly complicates the problem of designing a satisfactory automatic coupling, while to do away with them and substitute the combined buffer-coupling, such as is used in the United States, would entail enormous difficulties in carrying on the traffic during the transition stage.

Brakes.—In the United States the Safety Appliance Act of 1893 also forbade the railways, after the 1st of January 1898, to run trains which did not contain a “sufficient number” of cars equipped with continuous brakes to enable the speed to be controlled from the engine. This law, however, did not serve in practice to secure so general a use of power brakes on freight trains as was thought desirable, and another act was passed in 1903 to give the Interstate Commerce Commission authority to prescribe what should be the minimum number of power-braked cars in each train. This minimum was at first fixed at 50%, but on and after the 1st of August 1906 it was raised to 75%, with the result that soon after that date practically all the rolling stock of American railways, whether passenger or freight, was provided with compressed air brakes. In the United Kingdom the Regulation of Railways Act 1889 empowered the Board of Trade to require all passenger trains, within a reasonable period, to be fitted with automatic continuous brakes, and now all the passenger stock, with a few trifling exceptions, is provided with either compressed-air or vacuum brakes (see Brake), and sometimes with both. But goods and mineral trains so fitted are rare, and the same is the case on the continent of Europe, where, however, such brakes are generally employed on passenger trains.

(H. M. R.)

INTRA-URBAN RAILWAYS

The great concentration of population in cities during the 19th century brought into existence a class of railways to which the name of intra-urban may be applied. Such lines are primarily intended to supply quick means of passenger communication within the limits of cities, and are to be distinguished on the one hand from surface trams, and on the other from those portions of trunk or other lines which lie within city boundaries, although the latter may incidentally do a local or intra-urban business. Intra-urban railways, as compared with ordinary railways, are characterized by shortness of length, great cost per mile, and by a traffic almost exclusively passenger, the burden of which is enormously heavy. For the purpose of connecting the greatest possible number of points of concentrated travel, the first railways were laid round the boundaries of areas approximately circular, the theory being that the short walk from the circumference of the circle to any point within it would be no serious detention. It has been found, however, in the case of such circular or belt railways, that the time lost in traversing the circle and in walking from the circumference to the centre is so great that the gain in journey speed over a direct surface tramway or omnibus is entirely lost. Later intra-urban railways in nearly every case have been built, so far as possible, on straight lines, radiating from the business centre or point of maximum congestion of travel to the outer limits of the city; and, while not attempting to serve all the population through the agency of the line, make an effort to serve a portion in the best possible manner—that is, with direct transit.

The actual beginning of the construction of intra-urban railways was in 1853, when powers were obtained to build a line, 2½ mi. long, from Edgeware Road to King’s Cross, in London, from which beginning the Metropolitan and Metropolitan District railways developed. These railways, which in part are operated jointly, were given a circular location, but the shortcomings of this plan soon became apparent. It was found that there was not sufficient traffic to support them as purely intra-urban lines, and they have since been extended into the outskirts of London to reach the suburban traffic.

The Metropolitan and Metropolitan District railways followed the route of the old building as it existed at the time they were laid out. Wherever possible the lines were constructed in open cutting, to ensure adequate ventilation; and where this was not possible they were built by a method suggestively named “cut and cover.” A trench was first excavated to the proper depth, then the line and cored roof of brick were put in place, earth was filled in behind and over the arch, and the surface of the ground restored, either by paving where streets were followed, or by actually being built over with houses where the lines passed under private property. Where the depth to rail-level was too great for cut-and-cover methods, ordinary tunnelling processes were used; and where the trench was too shallow for the arched roof, heavy girders, sometimes of cast iron, bridged it between the side walls, longitudinal arches being turned between them (fig. 30).
by a single row of columns. The first actual work, however, was not begun till 1870, when the construction of an iron structure on a single row of columns was undertaken. The superiority, so far as the convenience of passengers is concerned, of an elevated over an underground railway, when both are worked by steam locomotives, and the great economy and rapidity of construction, led to the quick development and extension of this general design. By the year 1878 there were four parallel lines in the city of New York, and constructions of the same character had already been projected in Brooklyn and Chicago and, with certain modifications of details, in Berlin. In the year 1894 an elevated railway was built in Liverpool, and in 1900 a similar railway was constructed in Boston, U.S.A., and the construction of a new one undertaken in New York. These elevated railways as a rule follow the lines of streets, and are of two general types. One (fig. 31), the earliest form, consisted of a single row of columns supporting two lines of longitudinal girders carrying the rails, the lateral stability of the structure being obtained by anchoring the feet of the columns to their foundations. The other type (fig. 32) has two rows of columns connected at the top by transverse girders, which in turn carry the longitudinal girders that support the railway. In Berlin, on the Stadtbahn—which for a part of its length traverses private property—masonry arches, or earthen embankments between retaining walls, were substituted for the metallic structure wherever possible.

The next great development, marking the third step in the progress of intra-urban railway construction, took place in 1886, when J. H. Greathead (q.v.) began the City & South London railway, extending under the Thames from the Monument to Stockwell, a distance of 3½ m. Its promoters recognized the unsuitability of ordinary steam locomotives to work it by means of a moving cable; but before it was completed, electric traction had developed so far as to be available for use on such lines. Electricity, therefore, and not the cable, was installed (fig. 33). In the details of construction the shield was the novelty. In principle it had been invented by Sir Marc Isambard Brunel for the construction of the original Thames tunnel, and it was afterwards improved by Beach, of New York, and finally developed by Greathead. (For the details of the shield and method of its operation, see TUNNEL.) By means of the shield Greathead cut a circular hole at a depth ranging from 40 to 80 ft. below the surface, with an external diameter of 10 ft. 9 in.; this he lined with cast-iron segments bolted together, giving a clear diameter of 10 ft. 2 in. Except at the shafts, which were sunk on proposed station sites, there was no interference with the surface of the streets or with street traffic during construction. Two tunnels were built approximately parallel, each taking a single track. The cross-section of the cars was made to conform approximately to the section of the tunnel, the idea being that each train would act like a piston in a cylinder, expelling in front of it a column of air, to be forced up the station shaft next ahead of the train, and sucking down a similar column through the station shaft just behind. This arrangement was expected to ensure a sufficient change in air to keep such railways properly ventilated, but experience has proved it to be ineffective for the purpose. This method of construction has been used for building other railways in Glasgow and London, and in the latter city alone the “tube railways” of this character have a length of some 40 m. The later examples of these railways have a diameter ranging from 13 to 15 ft.

The fourth step in the development of intra-urban railways was to go to the other extreme from the deep tunnel which Greathead introduced. In 1893 the construction was completed in Budapest of an underground railway with a thin, flat roof, consisting of steel beams set close together, with small longitudinal jack arches between them, the street pavement resting directly on the roof thus formed (fig. 34). The object was to bring the level of the station platforms as close to the
RAILWAYS

In the operation of intra-urban railways, steam locomotives, cables and electricity have severally been tried: the first having been used in the earlier examples of underground lines and in the various elevated systems in the United States. The fouling of the air that results from the steam-engine, owing to the production of carbonic acid gas and of sulphurous fumes and aqueous vapour, is well known, and its use is now practically abandoned for underground working. The cable is slow; and unless development along new lines of compressed air or some sort of chemical engine takes place, electricity will monopolize the field. Electricity is applied through a separate locomotive attached to the head of the train, or through motor carriages attached either at one end or at both ends of the train, or by putting a motor on every axle and so utilizing the whole weight of the train for traction, all the motors being under a single control at the head of the train, or at any point of the train for emergency. The distance between stations on intra-urban railways is governed by the density of local traffic and the speed desired to be maintained. As a general rule the interval varies from one-quarter to one-half mile; on the express lines of the New York underground railway, the inter-station interval averages about 1½ m. On steam-worked lines the speed of trains is about 11 to 15 m. per hour, according to the distance between stations. Later practice takes advantage of the great increase in power that can be temporarily developed by electric motors during the period of acceleration; this, in proportion to the weight of the train to be hauled, gives results much in advance of those obtained on ordinary steam railways. Since high average speed on a line with frequent stops depends largely on rapidity of acceleration, the tendency in modern equipment is to secure as great an output of power as possible during the accelerating period, with corresponding increase in weight available for adhesion. With a steam locomotive all the power is concentrated in one machine, and therefore the weight on the drivers available for adhesion is limited. With electricity, power can be applied to as many axles in a train as desired, and so the whole weight of the train, with its load, may be utilized if necessary. Sometimes, as on the Central London railway, the acceleration of gravity is also utilized; the different stations stand, as it were, on the top of a hill, so that outgoing trains are aided at the start by having a slope to run down, while incoming ones are checked by the rising gradient they encounter.

The cost of intra-urban railways depends not only on the type of construction, but more especially upon local conditions, such as the nature of the soil, the presence of subsurface structures, like sewers, water and gas mains, electric conduits, &c.; the necessity of permanent underpinning or temporary supporting of house foundations, the cost of acquiring land passed under or over when street lines are not followed, and, in the case of elevated railways, the cost of acquiring easements of light, air and access, which the courts have held are vested in the abutting property. The cost of building an ordinary two-track elevated railway, according to American practice, varies from $300,000 to $400,000 a mile, exclusive of equipment, terminals or land damages. The cost of constructing the deep tubular tunnels in London, whose diameter is about 15 ft. exclusive, in like manner, of equipment, terminals or land damages, is about £170,000 to £200,000 a mile. The cost of the Metropolitan and Metropolitan District railways of London varied greatly on account of the variations in construction. The most difficult section—notably, that under Cannon Street—where the abutting buildings had to be underpinned, and a very dense traffic maintained during construction, while a network of sewers and mains was readjusted, cost at the rate of about £1,000,000 a mile. The contract price of the New York underground railway, exclusive of the incidentals above mentioned, was $35,000,000 for 21 m., of which 16 m. are underground and 5 are elevated. The most difficult portion of the road, 4½ m. of four-track line, cost $15,000,000.

(W. B. F.)

surface of the street as the height of the car itself would permit; in the case of Budapest the distance is about 9 ft. This principle of construction has since been followed in the construction of the Boston subway, of the Chemin de Fer Métropolitain in Paris, and of the New York underground railway. The Paris line is built with the standard gauge of 4 ft 8½ in., but its tunnels are designedly made of such a small cross-section that ordinary main line stock cannot pass through them.

The New York underground railway (fig. 35) marks a still further step in advance, in that there are practically two different railways in the same structure. One pair of tracks is used for a local service with stations about one-quarter of a mile apart, following the general plan of operation in vogue on all other intra-urban railways. The other, or central, pair of tracks is for trains making stops at longer distances. Thus there is a differentiation between the long-distance traveller who desires to be carried from one extreme of the city to the other and the short-distance traveller who is going between points at a much less distance.

To sum up, there are of intra-urban railways two distinct classes: the elevated and the underground. The elevated is used where the traffic is so light as not to warrant the expensive underground construction, or where the construction of an elevated line is of no serious detriment to the adjoining property. The underground is used where the congestion of traffic is so great as to demand a railway almost regardless of cost, and where the conditions of surface traffic or of adjoining property are such as to require that the railway shall not obstruct or occupy any ground above the surface.

Underground railways are of three general types: the one of extreme depth, built by tunnelling methods, usually with the shield and without regard to the surface topography, where the stations are put at such depth as to require lifts to carry the passengers from the station platform to the street level. This type has the advantage of economy in first construction, there being the minimum amount of material to be excavated, and no interference during construction with street traffic or subsurface structures; it has, however, the disadvantage of the cost of operation of lifts at the stations. The other extreme type is the shallow construction, where the railway is brought to the minimum distance below the street level. This system has the advantage of the greatest convenience in operation, no lifts being required, since the distance from the street surface to the station platform is about 12 to 15 ft.; it has the disadvantages, however, of necessitating the tearing up of the street surface during construction, and the readjustment of sewer, water, gas and electric mains and other subsurface structures, and of having the gradients partially dependent on the surface topography. The third type is the intermediate one between those two, followed by the Metropolitan and Metropolitan District railways, in London, where the railway has an arched roof, built usually at a sufficient distance below the surface of the street to permit the other subsurface structures to lie in the ground above the crown of the arch, and where the station platforms are from 20 to 30 ft. beneath the surface of the street—a depth not sufficient to warrant the introduction of lifts, but enough to be inconvenient.

FIG. 35.—New York Rapid Transit railway, showing also the tracks and conduits of the electric surface tramway.
Light Railways

The term light railways is somewhat vague and indefinite, and therefore to give a precise definition of its significance is not an easy matter. No adequate definition is to be found even in the British statute-book; for although parliament has on different occasions passed acts dealing with such railways both in Great Britain and Ireland, it has not inserted in any of them a clear and sufficient statement of what it intends shall be understood by the term, as distinguished from an ordinary railway. Since the passing of the Light Railways Act of 1896, which did not apply to Ireland, it is possible to give a formal definition by saying that a light railway is one constructed under the provisions of that act; but it must be noted that the commissioners appointed under that act have authorized many lines which in their physical characteristics are indistinguishable from street tramways constructed under the Tramways Act, and to these the term light railways would certainly not be applied in ordinary parlance.

Still, they do differ from ordinary tramways in the important fact that the procedure by which they have been authorized is simpler and cheaper than the methods by which special private acts of parliament have to be obtained for tramway projects. Economy in capital outlay and cheapness in construction is indeed the characteristic generally associated with light railways by the public, and implicitly attached to them by parliament in the act of 1896, and any simplifications of the engineering or mechanical features they may exhibit compared with the standard railways of the country are mainly, if not entirely, due to the desire to keep down their expenses.

The saving of cost is effected in two ways: (1) Instead of having to incur the expenses of a protracted inquiry before parliament, the promoters of a light railway under the act of 1896 make an application to the light railway commissioners, who then hold a local inquiry, to obtain evidence of the usefulness of the proposed railway, and to hear objections to it, and, if they are satisfied, settle the draft order and hand it over to the Board of Trade for confirmation. The Board may reject the scheme if it thinks the scheme to be of such magnitude or importance that it ought to come under the direct consideration of parliament, or it may modify it in certain respects, or it may remit it to the commissioners for further inquiry. But once the order is confirmed by the Board, with or without modifications, it has effect as if it had been enacted by parliament, and it cannot afterwards be upset on the ground of any alleged irregularity in the proceedings. (2) The second source of economy is to be sought in the reduced cost of actually making the line and of working it when made. Thus the gauge may be narrow, the line single, the rails lighter than those used in standard practice, while deep cuttings and high embankments may be avoided by permitting the curves to be sharper and the gradients steeper: such points conducing to cheapness of construction. Again, low speeds, light stock, less stringent requirements as to continuous brakes, signals, block-working and interlocking, road-crossings, stations, &c., tend to cheapness in working. On the other hand, however, the Board of Trade under the 1896 Act has fixed the normal minimum radius of the curves has been fixed at about 600 ft.; if a still smaller radius has been necessary, the speed has been reduced to 10 m. an hour and a guard-rail insisted on inside the curve. Again, the speed has been restricted to 20 m. an hour on long inclines with gradients steeper than 1 in 50, and also on a line which had scarcely any straight portions and in which there were many curves of 600 ft. radius and gradients of 1 in 50. In the case of a line of 2½ m. gauge, with a ruling gradient of 1 in 40, a maximum speed of 15 m. an hour and a minimum radius of curve of 300 ft. have been prescribed. Curves of still smaller radius have entailed a maximum speed of 10 m. an hour. It must be understood that a railway described as "light" is not necessarily built of narrower gauge than the standard. Many lines, indeed, have been designed on the normal 4 ft. 8½ in. gauge, and laid with rails weighing from 50 to 70 lb per yard; a flat-footed 60 lb rail, with the axle load limited to 14 tons, has the advantage for such lines that it permits the employment of a proportion of the locomotives used on main lines. The orders actually granted have allowed 36 lb, 56 lb, 60 lb and 70 lb rails, with corresponding axle-loads of 10, 12, 14 and 16 tons. On a line of 2 ft. gauge, rails of 40 lb have been sanctioned. In regard to fencing and precautions at level-crossings, less rigid requirements may be enforced than with standard railways; and in some cases where trains are likely to be few, it has been provided that the normal position of the gates at crossings shall be across the line. Again, if the speed is low and the trains infrequent, the signalling arrangements may be of a very simple and inexpensive kind, or even dispensed with altogether. It should be mentioned that the act provided that the Treasury might advance a portion of the money required for a line in cases where the council of any county, borough or district had agreed to do the same, and might also make a special advance in aid of a light railway which was certified by the Board of Agriculture to be beneficial to agriculture in any cultivated district, or by the Board of Trade to furnish a means of communication between a fishing-harbour and a market in a district where it would not be constructed without special assistance from the state.

As a general classification the commissioners have divided the schemes that have come before them into three classes: (A) those which like ordinary railways take their own line across country; (B) those in connexion with which it is proposed to use the public roads conjointly with the ordinary road traffic; and (Neutral) which includes inclined railways worked with a rope, and lines which possess the conditions of A and B in about equal proportions.

The Light Railways Act 1896 was to remain in force only until the end of 1901 unless continued by parliament, but it was continued year by year under the Expiring Laws Continuance Act. In 1901 the president of the Board of Trade introduced a bill to continue the act until 1906, and to amend it so as to make it authorize the construction of a light railway on any highway, the object being to abolish the restriction that a light railway should run into the area of at least two local authorities; but it was not proceeded with. Towards the end of 1901 a departmental committee of the Board of Trade was formed to consider the Light Railways Act, and in 1902 the president of the Board of Trade (Mr Gerald Balfour) stated that as a result of the deliberations of this committee, a new bill had been drafted which he thought would go very far to meet all the reasonable objections that had been urged against the present powers of the local authorities. This bill, however, was not brought forward. In July 1903, Lord Wolverton, on behalf of the Board of Trade, introduced a bill to continue and amend the Light Railways Act. It provided that the powers of the light railway commissioners should continue until determined by parliament, and also provided, inter alia, that in cases where the Board of Trade thought, under section (9) subsection (3) of the original act, that a proposal should be submitted to parliament, the Board of Trade itself might submit the proposals to parliament by laying in a bill for the confirmation of the light railway order, with a special report upon it. Opposition on petition could be heard before a select committee or a joint committee as in the case of private bills. The bill was withdrawn on the 11th of August 1903, Lord Morley appealing to the Board of Trade to bring in a more comprehensive measure to amend the unsatisfactory state of legislation in relation to tramways and light railways. In 1904 the president of the Board of Trade brought in a bill on practically the same lines as the amending bill of 1903. It reached second reading but was not proceeded with. Similar amending bills were introduced in the 1905 and 1906 sessions, but were withdrawn. During the first ten years after the act came into force 545 applications for orders were received, 313 orders were made, and 282 orders were confirmed. The orders confirmed were for 1731 m., involving an estimated capital expenditure of £12,770,384. At the end of 1906 only 500 m. had been opened for traffic, and the mileage of lines...
opened was much less in proportion to the mileage sanctioned in the cases of lines constructed on its own land than in the case of lines more of the nature of traffic lines. In the other countries where the mileage of main lines of railways in proportion to area and population is roughly the same as in the United Kingdom, the mileage of light railways already constructed is considerable, while many additional lines are under construction. At the end of 1903 there were 61,500 m. working in France, costing on an average £4,500 per mile, earning £75 per mile per annum; 37,300 miles in Prussia costing £180 per mile, earning £310 per mile per annum; 1,430 m. in Belgium at £340 per mile, earning £320 per mile per annum.)

The average cost per mile in Great Britain on the basis of the prescribed estimates is £5860, but this figure does not include the cost of equipment and does not cover the whole cost of construction. According to the light railway commissioners, experience satisfied them (a) that light railways were much needed in many parts of the country and that many of the lines proposed, but not constructed, were in fact necessary to the state and to the public interest; (b) that if improved means of access were requisite to the maintenance of the traffic of the lines and the communities which they served, they should find their way in the industrial centres, to cope with the difficulties as to housing and the whole question of the cost of labour. They pointed out that while during the first five years the act was in force there were 315 applications for orders, during the second five years there were only 142 applications, and that proposals for new lines had become less numerous owing to the various difficulties in carrying them to a successful completion and to the difficulties of the construction work itself. In conclusion, they must be regarded as the necessary and only means of bringing the public closer together and of making the railways more useful in all the areas in which they have been constructed.

The so-called light railways in the United States and the British colonies have been made under the conditions peculiar to those countries. Their primary object being the development and prosperity of the land, they have naturally been made as cheaply as possible; and even in such cases the cost of the land is not so much considered. In many cases the line is laid beside the road, with the road being used as the necessary power for rolling stock. Such railways are not "light" in the technical sense of having been made under enactments intended to secure permanent lowness of cost as compared with standard lines. On the continent of Europe many countries have encouraged railways which are light in that sense. France began to move in this direction in 1865, and has formulated elaborate provisions for their construction and regulation. Italy did the same in its laws in 1873, 1879, 1881, 1887 and 1889; and Germany fostered enterprise of this kind by the imperial edicts of 1875, 1878 and 1892. Holland, Hungary and Switzerland were all early in the field; and Belgium has succeeded, through the instrumentality of the semi-official Société Nationale de Chemins de Fer Vicinaux, started in 1885, in developing one of the most complete systems of rural railway transport in the world.

In France the lines which best correspond to British light railways are called chemins de fer d'interets locaux. These are regulated by a decree No. 11,264 of 6th August 1881, which the Ministry of Public Works is charged to carry out. The Ministry is further charged to work out the various scales of construction and the information to be shown thereon. For the first installation a single line is prescribed, but the concessionaire must provide space and be prepared to double when required. The gauge may be either 4 ft. 8½ in. (1 m.) or 3 ft. 6 in. (1.07 m.). The radius of curves for the 4 ft. 8½ m. gauge must not be less than 250 m., 100 m. for the 1 m. gauge and 50 m. for the 3 ft. 6 in. gauge. A straight length of not less than 60 m. for the 4 ft. 8½ m. gauge and 40 m. for the smaller gauge must be made between two curves having opposite directions. Except in special cases, gradients must not exceed 3 in 100; and between gradients in the opposite sense there must be no more than 60 m. of level for 144 m. and 40 m. for 1 m. and 75 m. gauges. The position of stations and stopping-places is regulated by the council of the department. The undertaking, once approved, is treated as a work of public utility. Any concessions are awarded with all the rights that a public department would have in the case of the carrying out of public works. At the end of the period of the concession the département comes into possession of the road and all its fixed appurtenances, and in the last five years of the term the département has the option of purchase of the line, and apply the revenue to putting it into a thorough state of repair. It has also the right to purchase the undertaking at the end of the first fifteen years, the net profits of the whole of the period to be taken into consideration. As far as possible, these railways are laid beside roads, in preference to independent formation; the permanent way costs £577 per mile in the former as against £793 in the latter. They are, therefore, the cheapest form of transport. The speed on the line is 176 m. per hour. Through villages, and where roads have to be crossed, the line is often at the usual tramway type. The line is of 1 m. gauge, with steel rails weighing 231 kg. (42 lb.) per yard. In the towns a deeper rail is used, weighing about 60 lb. per yard. In three lines the rails are laid on 3,500 kg. (7,700 lb.) axles, and the sharpest curves are 30 m. 35 m. and 40 metres respectively.

There are gradients of 1 in 20 and 1 in 25. The speed is limited to 30 kilometres (about 18 m.) in the country and 6 m. per hour in towns and through villages.

In Italy many railways which otherwise fulfil the conditions of a light railway are constructed with a gauge of 4 ft. 8½ in. The weights are governed by what the railway has to carry and the speed. Light locomotives, light rails and light rolling stock are employed. There are no bridges, except where watercourses occur. Cuttings are reduced to a minimum; and where the roads are sufficiently wide, the rails are laid on the margins of the roads. The whole system of use of the line is based on cheapness. No public transport is allowed on the main lines; the rolling stock is employed for goods which belong to the rolling stock of the main lines. In Italy these railways are called "economic railways," and are divided into five types. Types I, II, and III are 4 ft. 8½ in. gauge, type IV of 0-95 m. type V of 0-70 m. and type VI of 0-60 m. Each one, however, has the gauge of 1445 m. (4 ft. 8½ in.) and one of 0-95 (3 ft. 0-5 in.).

The chief difference between the first three types lies in the weight of rails and rolling stock and in the radius of the curves. The real light railways (type I) are constructed with a light weight of rails, 12 (26-45 kg.) to 20 (44 lb.) kilos; mean load per axle, 6 tons; minimum curve, 70 m. (229 ft. 2-6 in.); radius of formation, 30-50 m. (11 ft. 5-5 in.); top width of ballast, 2-10 m. (6 ft. 10-7 in.); depth of ballast under sleepers, 0-10 m. (3 ft. 9-5 in.); maximum gradient, 1 in 50; length of sleepers, 1-70 m. (5 ft. 6-2 in.); width between parapets and width of tunnels, 1 m. over width of carriage; height of tunnels, 5 m. (16 ft. 4-95 in.); locomotives, maximum weight 6 tons; maximum speed, 40 m. per hour (1 m. 10 ft. 10 in.); diameter of driving-wheels 1 m. (3 ft. 3-75 in.).

In Germany the use of light railways (klein-bahnken) has made great strides. The gauges in use vary considerably between 4 ft. 8½ in., the standard national gauge, and 1 ft. 11 in. German.
sleeper (which are of iron) are very portable, and skilled labour is not required to lay or to take them up; the making of a "turn-out" is easy, by taking out a 15 ft. section of the way and substituting a section with points and crossings. The safe load per wheel varies between 12 cwt. on a 10 in. 16 lb wheel and 40 cwt. on an 18 in. 56 lb wheel. The rolling stock is constructed either for farm produce or heavy minerals, the latter needing a 10 to 27 cub. ft. For timber, 4 or 5 ft. bogies can be used. A useful wagon for agricultural transport on a 24 in. gauge line is 16 ft. long by 5 ft. wide; it weighs 72 cwt. and costs £30. A portable line of this kind will have 20 lb steel rails and 2112 steel sleepers—4 ft. 6 in. long—to a mile, laid 2 ft. 6 in. apart centre to centre. The total cost per mile of such a line, including all bolts, nuts, fish-plates and fastenings, ready for laying, delivered in the United Kingdom, is under £500 a mile.

Seal Evans Austin of the Rainbow (1803), 1840, was issued to show the rules of the Board of Trade; W. H. Cole, Light Railways at Home and Abroad; Lieut.-Col. Addison, Report to the Board of Trade (1864) on Light Railways in Belgium. (C. E. W.; E. G. A.)

RAIMBACH, ABRAHAM (1776–1843). English line-engraver, a Swiss by descent, was born in London in 1776. Educated at Archibishop Tenison's Library School, he was an apprentice to J. Hall the engraver from 1789 to 1796. For nine years part of his working-time was devoted to the study of drawing in the Royal Academy and to executing occasional engravings for the booksellers, whilst his leisure hours were employed in painting portraits in miniature. Having formed an intimacy with Sir David Wilkie, Raimbach in 1812 began to engrave some of that master's best works. At his first Royal Academy exhibition in 1813, he heard a gold medal was awarded to him for his "Village Politicians" at the Paris Exhibition of 1814. He was elected corresponding member of the Institute of France in 1835.

RAIMUND, FERDINAND (1790–1836). Austrian actor and dramatist, was born on the 1st of June 1790, in Vienna. In 1812 he acted at the Josefštadter Theater, and in 1817 at the Leopoldstädter Theater. In 1823 he produced his first play, Der Barometermacher auf der Zaubersel, which was followed by Der Diamant des Geisterkönigs (1824) and the still popular Bayer als Millionär. The last-mentioned play, which appeared in 1826, Der Alpenkönig und der Menschenfeind (1828) and Der Verschwender (1832) are Raimund's masterpieces. He committed suicide on the 5th of September 1836, owing to the fear that he had been bitten by a mad dog. Raimund was a master of the verbal word or farce, his rich imagination being to best advantage in his realistic portraits of his fellow-citizens.

Raimund's Sämtliche Werke (with biography by J. N. Vogl) appeared in 4 vols. (1837); they have been also edited by K. Glossy and A. Sauer (4 vols., 1881; 2nd ed., 1891), and a selection by E. Castle (1905). See E. Schmidt in Charakterstichen, vol. i. (1886); A. Freiherr von Pobietzl (in Raimund's Centenary, 1884); L. A. Franck, Zur Biographie F. Raimunds (1884); and especially A. Sauer's article in the Allgem. Deutsche Biographie.

RAIN (O.E. regn; the word is common to Teutonic languages, cf. Ger. Regen, Swed. and Dan. regn; it has been connected with Lat. rigare, to wet, Gr. ἱρας, the water vapour of the atmosphere when condensed into drops large enough to be precipitated upon the earth. Hence the term is extended to signify the fall of such drops in a shower, and in the plural, "the rains," it signifies the rainy seasons in India and elsewhere where under normal climatic conditions such seasons are clearly distinguished from the dry. A rain-band is "a dark band in the solar spectrum, caused by the presence of water-vapour in the atmosphere" (New Engl. Dict.); a rain-gauge is an instrument used to measure the amount of rainfall (see Meteorology, where the whole subject of precipitation is fully treated).

RAINBOW, formerly known as the iris, the coloured rings seen in the heavens when the light from the sun or moon shines on falling rain; on a smaller scale they may be observed when sunshine falls on the spray of a waterfall or fountain. The bows assume the form of concentric circular arcs, having their common centre on the line joining the eye of the observer to the sun. Generally only one bow is clearly seen; this is known as the primary rainbow; it has an angular radius of about 41°, and exhibits a fine display of the colours of the spectrum, being red on the outside and violet on the inside. Sometimes an outer bow, the secondary rainbow, is observed; this is much fainter than the primary bow, and it exhibits the same play of colours, with the important distinction that the order is reversed, the red being inside and the violet outside. Its angular radius is about 50°. It is also to be noticed that the space between the two bows is considerably darker than the rest of the sky. In addition to these prominent features, there are sometimes to be seen a number of coloured bands, situated at or near the summits of the bows, close to the inner edge of the primary and the outer edge of the secondary bow; these are known as the spurious, supernumerary or complementary rainbows.

The formation of the rainbow in the heavens after or during a shower must have attracted the attention of man in remote antiquity. The earliest references are to be found in the various accounts of the Deluge. In the Biblical narrative (Gen. ix., 17–17) the bow is introduced as a sign of the covenant between God and man, a figure without a parallel in the other accounts. Among the Greeks and Romans various speculations as to the cause of the bow were indulged in; Aristotle, in his Meteor, erroneously ascribes it to the reflection of the sun's rays by the rain; Seneca adopted the same view. The introduction of the idea that the phenomenon was caused by refraction is to be assigned to Vitellio. The same conceit was utilized by Theodicor of Vribia, a Dominican, who wrote at some time between 1304 and 1311 a treatise entitled De radiatis impressionibus, in which he showed how the primary bow is formed by two refractions and one internal reflection; i.e. the light enters the drop and is refracted; the refracted ray is then reflected at the opposite side of the drop, and leaves the drop at the same side at which it enters, being again refracted. It is difficult to determine the influence which the writings of Theodicor had on his successors; his works were apparently unknown until they were discovered by G. B. Venturi at Basel, partly in the city library and partly in the library of the Dominican monastery. A full account, together with early other contributions to the science of light, is given in Venturi's Commentari sopra la storia de la Teoria de l'Otica (Bologna, 1814). John Fleischer (sometimes incorrectly named Fletcher), of Breslau, propounded the same view in a pamphlet, De iridibus doctrina Aristotelis et Vitelloni (1754); the same explanation was given by Francisca Maurolycus in his Phaenomena luminum et umbrae (1575).

The most valuable of all the earlier contributions to the scientific explanation of rainbows is undoubtedly a treatise by Antonio de Dominis (1566–1624), archbishop of Spalatro. This work, De radiis visus et lucis in vitris perspective et iride, published at Venice in 1611 by J. Bartolius, although written some twenty years previously, contains a chapter entitled "Vera iridis tota generatio explicatio," in which it is shown how the primary bow is formed by two refractions and one reflection, and the secondary bow by two refractions and two reflections. Descartes strengthened these views, both by experiments and geometrical investigations, in his Meteor (Leiden, 1637). He employed the law of refraction (discovered by W. Snellius) to calculate the radius of the bows, and his theoretical angles were in agreement with those observed. His methods, however, were not free from tentative assumptions, and were considerably improved by Edmund Halley (Phil. Trans., 1700, 74). Descartes, however, could advance no satisfactory explanation of the chromatic displays; this was effected by Sir Isaac Newton, who, having explained bow white light is composed of rays possessing all degrees of refrangibility, was enabled to demonstrate that the order of the colours was in perfect accord with the requirements of theory (see Newton's Opticks, book i. part 2, prop. 9).

The geometrical theory, which formed the basis of the investigations of Descartes and Newton, afforded no explanation of the supernumerary bows, and about a century elapsed before an explanation was forthcoming. This was given by Thomas Young, who, in the Bakerian lecture delivered before the Royal Society on the 24th of November 1803, applied his principle
of the interference of light to this phenomenon. His not wholly satisfactory explanation was mathematically examined in 1835 by Richard Potter (Camb. Phil. Trans., 1838, 6, 141), who, while improving the theory, left a more complete solution to be made in 1838 by Sir George Biddell Airy (Camb. Phil. Trans., 1838, 6, 379).

The geometrical theory first requires a consideration of the path of a ray of light falling upon a transparent sphere. Of the total amount of light falling on such a sphere, part is reflected or scattered at the incident surface, so rendering the drop visible, while a part will enter the drop. Confining our attention to the ray which has fallen upon the principal plane, we will determine its deviation, i.e., the angle between its directions of incidence and emergence, after one, two, three, or more internal reflections. Let EA be a ray incident at an angle i to the principal plane, AD the reflected ray, and r the angle of refraction. Then the deviation experienced by the ray at A is i = r. If the ray suffers one internal reflection at D, then it is readily seen that, if DB be the path of the reflected ray, the angle ADB equals 2r, i.e., the deviation of the ray at D is π − 2r. At B, where the ray leaves the drop, the deviation is the same, viz., i = r.

The total deviation of the ray is consequently given by D = (2i − r) + π + 2r = π + r. Similarly it may be shown that each internal reflection introduces a supplementary deviation of π − 2r, hence, if the ray be reflected n times, the total deviation will be D = (2i − r) + nπ + (n − 2)r = π + nπ − 2r.

This deviation is thus seen to vary with the angle of incidence; and by considering a set of parallel rays passing through the same principal plane of the sphere and incident at all angles, it can be readily shown that the deviations will be greatest at the position of minimum deviation than in any other position (see Refraction). The drop will consequently be more intensely illuminated when viewed along these directions of minimum deviation, and since it is these rays with which we are primarily concerned, we shall proceed to the determination of these directions.

Since the angles of incidence and refraction are connected by the relation sin i = μ sin r (Snell’s Law), μ being the index of refraction of the medium, then in the case of a drop, we have the following to determine the value of the angle i which makes D = 2i − r + nπ − 2r a maximum or minimum, in which i and r are connected by the relation sin i = μ sin r, μ being a constant. By applying the method of the differential calculus, we find that μ must be at least unity for a rainbow to be formed; there is obviously no theoretical limit to the value of μ, and hence rainbows of higher orders are possible.

So far we have only considered rays of homogeneous light, and it remains to investigate how light of varying refrangibilities will be transmitted. It can be shown, by the methods of the differential calculus or geometrically, that the deviation increases with the refractive index, the angle of incidence remaining constant. Taking the refractive index of water for the red rays as 4/3, and for the violet rays as 4/3, we can calculate the following values for the minimum deviations corresponding to certain assigned values of μ.

To this point we have only considered rays passing through a principal section of the drop; in nature, however, the rays impinge at every point of the surface facing the sun. It may be readily deduced that the directions of minimum deviation for a pencil of parallel rays lie on the surface of cones, the semi-vertical angles of which are four times greater than the corresponding values given above. If a ray suffering one internal reflection will all lie within a cone of about 42°; in this direction the illumination will be most intense; within the cone the illumination will be fainter, while, without it, no light will enter the eye.

Fig. 2 represents sections of the drop and the cones containing the minimum deviation rays at 1, 2, 3, and 4 reflections; the order of the colours is shown by the letters R (red) and V (violet). It is apparent, therefore, that all the rays transmitting intense light after one internal reflection to the eye will lie on the surfaces of cones having the eye for their common vertex, the line joining the eye to the sun for their axis, and their semi-vertical angles equal to about 41° for the violet rays and 45° for the red rays. The observer will, therefore, see a coloured band, about 2° in width, and coloured violet inside and red outside. Within the band, the illumination will be faint; outside the band there will be perceptible darkening until the second bow comes into view. Similarly, drops transmitting rays after two internal reflections will be situated on covetrical cones of the same order as those just considered for the red rays, and 54° for the violet. Outside the cone of 54° there will be faint illumination; within it, no secondary rays will be transmitted to the eye. We thus see that the order of colours in the secondary bow is the reverse of that in the primary; the secondary is half as broad again (3°), and much fainter, owing to the longer path of the ray in the drop, and the increased dispersion.

Similarly, the third, fourth and higher orders of bows may be investigated. The third and fourth bows are situated between the observed and suggested by Thomas Young. No observer must face the sun. But the illumination of the bow is so weakened by the repeated reflections, and the light of the sun is generally so bright, that these bows are rarely, if ever, observed except in artificial bows such as those formed by a beam of sunlight shining for a moment on a drop of water. This overlapping may become so pronounced as to produce a rainbow in which colour is practically absent; this is particularly so when a thin cloud intervenes between the sun and the rain, which may have the surface of incision. It will sometimes be as much as 2° or 3°. This phenomenon is known as the "white rainbow" or "Ulloa’s Ring or Circle," after Antonio de Ulloa.

We have now to consider the so-called spurious bows which are sometimes seen at the external edge of the primary and at the outer edge of the secondary bow. The geometrical theory can afford no explanation of these coloured bands, and it has been shown that the complete phenomenon of the rainbow can be sought for in the conceptions of the wave theory of light.

Physical theory.

This theory was first suggested by Thomas Young, who observed that the rays producing the bows consisted of two systems, which, although emerging in parallel directions, traversed different paths in the drop. Destructive interference between these superposed rays will therefore occur, instead of the addition in intensity which we found in the case of the primary bow. Airy showed that the secondary bow is not situated directly on the line of minimum deviation, but at a slightly greater value; this means that the true angular radius of the bow is a little less than that arrived from the geometrical theory. In the same way, he showed that the secondary bow has a greater radius than that previously assigned to it. The spurious bows he showed to consist of a series of dark and bright bands, whose distances from the principal bows vary with the diameters of the raindrops. The smaller the drops, the greater the distance; hence it is that the spurious bows are generally only observed near the summits of the bows, where the drops are smaller than at any lower altitudes. In Airy’s investigation, and in the extensions by Beitel, J. Larmor, E. Mascart and E. Lorentz, the source of light was regarded as a point. In nature, however, this is not realized, for the sun has an appreciable diameter. Calculations taking this into account have been made by J. Pernter (Naturwiss. über den Regenbogen, Vienna, 1888) and by K. Aichi and T. Tanakadate (Jour. Coll. of Science, Tokyo, 1906, vol. xxi, art. 3).

Experimental confirmation of Airy’s theoretical results was afforded in 1892 by Wilhelm Mascart (Camb. Phil. Trans., v ii, 1888, 277). A horizontal pencil of sunlight was admitted by a vertical slit, and then allowed to fall on a column of water supplied by a jet of about 6° of an inch in diameter. Primary, secondary and spurious bows were formed, and their radii measured; a comparison of their dimensions with Airy’s analytical values. Pulfrich (Wied. Ann., 1888, 33, 194) obtained similar results by using cylindrical glass rods in place of the column of water. In accordance with a general consequence of refraction and refraction, it is readily seen that the light of the rainbow is partially polarized, a fact first observed in 1811 by Jean Baptiste Biot (see Polarization).
Lunar rainbows. The moon can produce rainbows in the same manner as the sun. The colours are much fainter, and according to Aristotle, who claims to be the first observer of this phenomenon, the lunar bows are only seen when the moon is full. Marine rainbows is the name given to the chromatic displays formed by the sun's rays falling on the spray drawn up by the wind playing on the surface of an agitated sea.

Intersecting rainbows are sometimes observed. They are formed by parallel rays of light emanating from two sources, as for example, the sun and its immediate sheet of water, which is situated between the observer and the sun. In this case the second bow is much fainter, and has its centre as much above the horizon as that of the direct system is below.

RAINOLDS—RAI

RAI PUR, a town and district of British India, in the Chhattisgarh division of the Central Provinces. The town is 904 ft. above sea-level, 188 m. E. of Nagpur; and has a station on the Bengal-Nagpur railway. Pop. (1901) 32,114. There are ruins of an immense fort, with many tanks and old temples. It has a German mission and a government high school. The Rajkumar college, for the education of the sons of the chiefs of Chhattisgarh, was transferred here from Jubbulpore in 1894.

The District of Raipur has an area of 9,831 sq. m. It spreads over a vast plateau closed in by ranges of hills branching from the great Vindhyan chain. It is drained by the Seonath and the Mahanadi rivers. Geologically the country consists in the hilly tracts of gneiss and quartzite; the sandstone rocks in the west are intersected with trap dykes. Iron ore is abundant, and red ochre of high repute is found. In the interior the principal strata are a soft sandstone slate (covered generally by a layer of laterite gravel) and blue limestone, which crops out in numerous places on the surface and is invariably found in the beds of the rivers. Throughout the plains the soil is generally fertile. The climate is generally good; the mean temperature is 70° F., and the annual rainfall averages 55 in.

The population on the present area in 1901 was 1,096,838, showing a decrease of 2.5% in the decade. The principal crop is rice. There are manufactures of cotton goods and brassware.

The north-west corner of the district is crossed by the main line of the Bengal-Nagpur railway, and a narrow-gauge branch runs from Raipur town due south. The district suffered severely from famine in 1896-97, and again in 1899-1900.

Raipur was governed by a branch of the Haihaivani dynasty of Ratanpur for many centuries until their deposition by the Mahtrattas in 1750. The country was then already in a condition of decay, and soon afterwards it relapsed into absolute anarchy. In 1818 it was taken under British superintendence and made rapid progress. It fell with the rest of the Nagpur dominions to the British government in 1854. In 1906 its area was reduced by the formation of the new district of Drug.

RAIS (or REITZ), GILLES DE (1404-1440), marshal of France and the central figure of a 15th-century cause célèbre, whose name is associated with the story of Bluebeard, was the son of Guy de Montmorency-Laval, the adopted son and heir of Jeanne de Rais and of Marie de Craon. He was born at Machecoul in September or October 1404, and, being early left an orphan, was educated by his maternal grandfather, Jean de Craon. Chief among his great possessions was the barony of Rais (erected in the 16th century into the peerage-duchy of Retz), south of the Loire, on the marches of Brittany. He joined the party of the Montforts, supporting Jean V. of Brittany against the rival house of Penthièvre. He helped to release Duke John from Olivier de Blois, count of Penthièvre, who had taken him prisoner by craft, and was rewarded by extensive grants of land, which were subsequently commuted by the Breton parliament for money payments. In 1420, after other projects of marriage had fallen through, in two cases by the death of the bride, he married Katherine of Thouars, a great heiress in Brittany, La Vendée and Poitou. In 1426 he raised seven companies of men-at-arms, and began active warfare against the English under Artus de Richemont, the newly made constable of France. He had already built up a military reputation when he was chosen to accompany Joan of Arc to Orleans. He continued to be her special protector, fighting by her side at Orleans, and afterwards at Jargeau and Patay. He had advocated further measures against the English on the Loire before carrying out the coronation of Charles VII. at Reims. On the 17th of July he was made marshal of France at Reims, and after the assault on Paris he was granted the right to bear the arms of France as a border to his shield, a privilege that was, however, never ratified. In the winter he was in Normandy, at Louviers, whether with a view to the release of Joan, then a prisoner at Rouen, cannot be stated. Meanwhile his fortune was disappearing, although he had been one of the richest men in France. He had expended great sums in the king's service, and he maintained a court of
knights, squires, heralds and priests, more suited to royal than baronial rank. He kept open house, was a munificent patron of literature and of music, and his library contained many valuable works, he himself being a skilled illuminator and binder. He also indulged a passion for the stage. At the chief festivals he gave performances of mysteries and moraetals, and it has been asserted that the Mystere de la Passion, acted at Angiers in 1420, was staged by him in honour of his own marriage. The original draft of the Mystery of Orleans was probably written under his direction, and contains much detail which may be well accounted for by his intimate acquaintance with the Maid. In his financial difficulties he began to alienate his lands, selling his estates for small sums. These proceedings provided his heirs with material for lawsuits for many years. Among those who profited by his prodigality were the duke of Brittany, and his chancellor, Jean de Malestroit, bishop of Nantes, but in 1436 his kinsfolk appealed to Charles VII., who procured further sales to be illegal. Jean V. refused to acknowledge the king's right to promulgate a decree of this kind in Brittany, and replied by making Gilles de Raiss lieutenant of Brittany and by acknowledging him as a brother-in-arms. Gilles hoped to redeem his fortunes by alchemy; he also spent large sums on neercmanners, who engaged to raise the devil for his assistance. On the other hand he sought to guarantee himself from evil consequences by extravagant charity and a splendid celebration of the rites of the church. The abominable practices of which he was really guilty seem not to have been suspected by his equals or superiors, though he had many accomplices and his criminality was suspected by the peasantry. His wife finally left him in 1434-35, and may possibly have become acquainted with his doings, and when his brother René de la Suze seized Champèce, all traces of his crimes had not been removed, but family considerations no doubt imposed silence. His servants kidnapped children, generally boys, on his behalf, and these he tortured and murdered. The number of his victims was stated in the ecclesiastical trial to have been 140, and larger figures are quoted. The amazing impunity which he enjoyed was brought to an end in 1440, when he was imprudent enough to come into conflict with the church by an act of violence which involved sacrilege and infringement of clerical immunity. He had sold Saint Etienne de Malemort to the duke of Brittany's treasurer, Géfron le Ferron. In the course of a quarrel over the delivery of the property to this man's brother, Jean le Ferron, Gilles seized Jean, who was in clerical orders, in church, and imprisoned him. He then proceeded to defy the duke, but was reconciled to him by Richelieu. In the autumn, however, he was arrested and cited before the bishop of Nantes on various charges, the chief of which were heresy and murder. With the latter count the ecclesiastical court was incompetent to deal, and on the 5th of October Gilles refused to accept its jurisdiction. Terrified by excommunication, however, he acknowledged the evidence and was released on payment of a fine of 1,200 gold francs. He had been pronounced guilty of apostasy and heresy by the inquisitor, and of vice and sacrilege by the bishop. A detailed confession was extracted by the threat of torture on the 21st of October. A separate and parallel inquiry was made by Pierre de l'Hôpital, president of the Breton parliament, by whose sentence he was hanged (not burned alive as is sometimes stated), on the 26th of October 1440, with two of his accomplices. In view of his own repeated confessions it seems impossible to doubt his guilt, but the numerous irregularities of the proceedings, the fact that his neercomane Prelai and other of his chief accomplices went unpunished, taken together with the financial interest of Jean V. in his ruin, have left a certain mystery over a trial, which, with the exception of the process of Joan of Arc, was the most famous in 15th-century France. His name is connected with the tale of Bléubeard (p.v.) in local tradition at Machecoul, Tiffauges, Pornic and Chéméré, though the similarity between the two histories is at best vague. The records of the trial are preserved in the Bibliothèque Nationale in Paris, at Nantes and elsewhere.

See Eugène Bossard, Gilles de Raiss, dit Barbe Bleue (2nd ed., 1886), which includes the majority of the documents of the trial published originally by De Maleulde; E. A. Vezetelly, Bluebeard (1902); H. C. Lea, Hist. of the Inquisition (iii. 408, 409); A. Mollinet, Les Sources de l'histoire de France et de l'Italie aux temps des Prêtres, describes his hero as engaged on a life of Gilles de Raiss, and takes the opportunity for a striking picture of the trial.

RAISIN

(Rf. raisin, grape; Lat. racemas), the name given to the dried fruits of certain varieties of the grape vine, Vitis vinifera, which grow principally in the warm climate of the Mediterranean coasts and are comparatively rich in sugar. The use of dried grapes or raisins as food is of great antiquity (Num. vi. 3; 1 Sam. xxv. 18, xxx. 12). In medieval times raisins imported from Spain were a prized luxury in England, and to the present day Great Britain continues to be the best customer of the raisin-producing regions. "Raisins of the sun" are obtained by letting the fruit continue on the vines after it has come to maturity, where there is sufficient sunshine and heat in the autumn, until the clusters dry on the stocks. Another plan is partially to sever the stalks before the grapes are quite ripe, thus stopping the flow of the sap, and in that condition to leave them on the vines till they are sufficiently dry. The more usual process, however, is to cut off the fully ripe clusters and expose them, spread out, for several days to the rays of the sun, taking care that they are not injured by rain. In unfavourable weather they may be dried in a heated chamber, but are then inferior in quality. In some parts of Spain and France it is common to dip the gathered clusters in boiling water, or in a strong potash lye, a practice which softens the skin, favours drying and gives the raisins a clear glossy appearance. Again, in Asia Minor the fruit is dipped into hot water on the surface of which swims a layer of olive oil, which communicates a bright lustre and softness to the skin. Some superior varieties are treated with very great care, retained on their stalks, and sent into the market as clusters for table use; but the greater part are separated from the stalks in the process of drying and the stalks winnowed out of the fruit. Raisins come from numerous Mediterranean localities, and present at least three distinct varieties—(1) ordinary or large raisins, (2) sultana seedless raisins, and (3) currants or Corinthian raisins (see CURRENT). The greater proportion of the common large raisins of English commerce comes from the provinces of Malaga, Valencia and Alicante in Spain; these are known by the common name of Malaga raisins. Those of the finest quality, called Malaga clusters, are prepared from a variety of muscatel grape, and preserved on the stalks for table use. This variety, as well as Malaga layers, so called from the manner of packing, are exclusively used as dessert fruit. Raisins of a somewhat inferior quality, known as "lexias," from the same provinces, are used for cooking and baking purposes. Smyrna raisins also come to some extent into the English market. The best quality, known as Élemé, is a large fruit, having a reddish-yellow skin with a sweet pleasant flavour. Dark-coloured raisins are produced on some of the islands of the Greek archipelago and in Crete, but they are little seen in the British markets. In Italy the finest raisins are produced in Calabria, inferior qualities in central Italy and in Sicily. From the Lipari Islands a certain quantity of cluster raisins of good quality is sent to England. In the south of France raisins of high excellence—Provence raisins in clusters—are obtained at Roquevaire, Lunel and Frontignan. Sultana seedless raisins are the produce of a small variety of yellow grape, cultivated exclusively in the neighbourhood of Smyrna. The vines are grown on a soil of decomposed hippurite limestone, on sloping ground rising to a height of 400 ft. above the sea, and all attempts to cultivate sultanas in other raisin-growing localities have failed, the grapes quickly reverting to a seed-bearing character. The dried fruit has a fine golden-yellow colour, with a thin, delicate, translucent skin and a sweet aromatic flavour. A very fine seedless oblong raisin of the sultana type, with a brownish skin, is cultivated in the neighbourhood of Damascus.
RAJA—RAJPUT 865

RAJA, the Hindu title for a chief, or prince, derived from the same root as the Latin rex. Other forms are rao, rana and rawal, while chiefs of high rank are styled maharaja, maharao and maharana. The Hindustani form is rai, and the title of the Hindu emperor of Vijayanagar in S. India was raya. It is not confined to the rulers of native states, being conferred by the British government on Hindu subjects, sometimes as an hereditary distinction. In the form of rao it appears as a suffix to the names of most Maharras, and to the names of Kanarese Brahmanas.

RAJAHMUNDRY, or RAJMAHENDRI, a town of British India, in the Godavari district of Madras. Pop. (1901) 36,408. It stands on the left bank of the river Godavari, at the head of the delta, 360 m. N. of Madras, and has a station on the East Coast railway, which is here carried across the river by a bridge of 56 spans. The government college is one of the four provincial schools established in 1853. There are also a training college and high school. Carpets, rugs and wooden wares are manufactured.

RAJASTHAN is a district of a great extent, divided into the principal parts of central and northern India, and has several dialects the principal of which are Jaipur, Mârwarî, Mâhâwarî and Malvi. Hâraju, an important variety of Jaipur, is spoken in the states of Kota and Bundi. Carey, the well-known Serum- pûr missionary, paid great attention to Rajasthani in the early part of the 19th century, translating the New Testament into no fewer than six dialects, viz. Hârâju, Ujaini (i.e. Malvi), Udaipurî (a form of Mâhâwarî), Mârwarî proper, Jaipur proper and Bîlkaneri (another form of Mârwarî). In 1901 the total number of speakers of Rajâsthâni was 10,917,712. (G. A. G.)

RAJGHAR, a native state of central India, in the Bhopal agency. Area, 940 sq. m. Pop. (1901) 88,376, showing a decrease of 26% in the decade, due to the results of famine. Estimated revenue, £33,000; tribute to Sindhis, £3,630. The chief, whose title is rawat, is a Rajput of the Umar clan. Grain and opium are the principal articles of trade. The town of Rajgarh, which is surrounded by a battlemented wall, had a population of 5390 in 1901.

RAJKOT, India, capital of a native state in Bombay, and headquarters of the political agent for Kathiawar. Pop. (1901) 36,151. It is situated in the middle of the peninsula of Kathiawar, and is the centre of the railway system. There is a military cantonment. The Rajkumar college, for the education of the sons of chiefs on the lines of an English public school, has achieved great success. Besides the high school there are training colleges for masters and mistresses. The Rasulkhanji hospital has a department for women, opened in 1897. All these institutions are maintained at the joint expense of the chiefs of Kathiawar. The state of Rajkot, which is a branch of Nawanagar, has an area of 282 sq. m. Pop. (1901) 49,795. Estimated revenue, £23,000.

RAJMAHAL, a former capital of Bengal, India, now a village in the district of the Santal Parganas, situated on the right bank of the Ganges, where that river makes a turn to the south. Pop. (1901) 2047. It was chosen for his residence by Man Singh. Akbar's Rajput general in 1592, but the capital of the province was shortly afterwards transferred to Dacca. It contains many palaces and mosques, now in ruins and overgrown with jungle. It has a station on the loop line of the East Indian railway, but trade has declined since the Ganges abandoned its old bed; and Sahibganj has taken its place. Rajmahal has given its name to a range of hills, almost the only hills in Bengal proper, which here come down close to the bank of the Ganges. They cover a total area of 1566 sq. m., and their height never exceeds 2000 ft. They are inhabited by an aboriginal race, known as Paharias or "hill-men," of whom two tribes may be distinguished: the Maia Sauria Paharias and the Mal Paharias; total pop. (1901) 73,000. The former, if not the latter also, are closely akin to the larger tribe of Oraons. Their language, known as Malto, of the Dravidian family, was spoken by 60,777 persons in 1901. The Paharias have contributed an element to the administrative history of Bengal. Augustus Cleveland, a civilian who died in 1784 and whose name is still honoured, was the first who succeeded in winning their confidence and recruiting among them a corps of hill-rangers. The methods that he adopted are the foundation of the "non-regulation" system, established in 1796; and the hills were exempted from the permanent settlement. The Santals, a different aboriginal race, have since immigrated in large numbers into the Damai-i-koh, or "skirts of the hills"; but the Paharias alone occupy the plateaux on the top, where they are permitted to practise the privilege of shifting cultivation, which renders scientific forestry impossible. The approach from the plains below to each plateau is guarded by a steep ladder of boulders.

See E. W. Dalton, Descriptive Ethnology of Bengal (Calcutta, 1872); F. B. Bradley-Birt, The Story of an Indian Upland (1905).

RAJPIPLA, a native state of India, in the Rewa Kantha agency, Bombay, occupying a hilly tract between the rivers Nerbudda and Tapti; area, 1317 sq. m. Pop. (1901) 117,175, showing a decrease of 3% in the decade, due to the results of famine; estimated revenue, £60,000; tribute to the Gaekwar of Baroda, £900. The chief, whose title is maharana, is a Gohel Rajput, of the same family as the thakor saheb of Bhuanagar. A light railway, constructed at the cost of the state, connects Nandod with Anklesvar in Broach district. The old fort of Rajipla, in the hills, is now deserted. The modern capital is Nandod, situated on the river Karjan, 32 m. from Surat. Pop. (1901) 11,236.

RAJPUT, a race of India, not confined to Rajputana, but spread over the N. of the country. According to the census of 1901 there were 9,712,156 Rajputs in all India, of whom only 620,229 lived in Rajputana. The great majority adhere to the Hindu religion, but 1,875,387 are entered as Mahommades. The Rajputs form the fighting, landowning and ruling caste. They claim to be the modern representatives of the Kshatriyas of ancient tradition; but their early history is obscure, and recent research supports the view that they include descendants of both the aboriginal and of immigrant invaders. Linguistic evidence supports tradition in proving that the Kshatriya was broken up by the Mahommaded conquest, for the inhabitants of the Himalayan valleys still speak a language akin to those of Rajputana proper, though separated from them by the wide Gangetic valley.

The Rajputs are fine, brave men, and retain the feudal instinct strongly developed. Pride of blood is their chief characteristic, and they are most punctilious on all points of etiquette. The tradition of common ancestry permits a poor Rajput yeoman to consider himself as well born as any powerful landholder of his clan, and superior to any high official of the professional classes.

No race in India can boast of finer feats of arms or brighter deeds of chivalry, and they form one of the main recruiting fields for the Indian army of to-day. They consider any occupation other than that of arms or government derogatory to their dignity, and consequently during the long period of peace which has followed the establishment of the British rule in India they have been content to stay idle at home instead of taking up any of the other professions in which they might have come to the front. Those who are not zamindars have, therefore, rather dropped behind in the modern struggle for existence. As cultivators they are lazy and indifferent, and they prefer pastoral to agricultural pursuits. Looking upon all manual labour as humiliating, none but the poorest class of Rajput will himself hold the plough.

XXII. 28
Within the limits of Rajputana the Rajputs form a vast body of kindred, and any Rajput can marry any Rajput woman who does not belong to his own clan. The most numerous of the clans is the Rahtor, to which the chiefs of Marwar, Bikainar and Kishangarh belong. Its strength in 1901 was 122,160. Next comes the Kachwaha clan, which is strong in Jaipur and Alwar, both chiefs belonging to its members. It numbers 100,186. The Chauhan follows with an aggregate of 86,460, among whom are the chiefs of Bundi, Kotah and Sirohi. The Jodhpur and Jodhan, which includes in its ranks the chiefs of Karauli and Jaisalmear, numbers 74,666. The Sidodhyas, who include the ancient and illustrious house of Udaipur, number 51,666. The Poonwar clan, to which Vikramaditya, the celebrated king of Ujjain, from whom the Hindu Era is named, is said to have belonged, numbers 43,435. The Solanki and Parhar clans, once powerful, are now only 9,448 and 9,448 respectively.

Rajputana, a collection of native states in India, under the political charge of an agent to the governor-general, who resides at Abu in the Aravalli Hills. It lies between 23° and 30° N. and between 69° 30' and 75° 15' E., and includes 18 states and 2 estates or chiefships. For political purposes these are subdivided into eight subordinate groups, consisting of three residues and five agencies. These are as follows: (1) Mewar residency, with headquarters at Udaipur, comprising the states of Udaipur (Mewar), Dungarpur, Partabgarh and Banswara; (2) Jaipur residency, with headquarters at Jaipur, comprising the states of Jaipur and Kishangarh, with the estate of Lawa; (3) Western Rajputana states residency, with headquarters at Jodhpur, comprising the states of Jodhpur, Jaisalmer and Sirohi; (4) Bikainar agency, with headquarters at Bikainar; (5) Alwar agency, with headquarters at Alwar; (6) Eastern Rajputana states agency, with headquarters at Bharatpur, comprising the states of Bharatpur, Dholpur, and Karauli; (7) Harot-Toon agency, with headquarters at Deoli, comprising the states of Tonk and Bundi, with the estate of Shahpura; (8) Kotah-Jhalawar agency, with headquarters at Kotah, comprising the states of Kotah and Jhalawar. All of these states are under Rajput rulers, except Tonk, which is Mahommedan, and Bharatpur and Dholpur, which are Jat. The small British province of Ajmere-Merwara is also included within the geographical area of Rajputana.

Physical Features.—The total area of Rajputana is about 127,541 sq. m. It is bounded on the west by Sind, and on the north-west by the Bhawalwa range of hill-ranges, which forms the eastern frontier marches with the Punjab and the United Provinces until it touches the river Chambal, where it turns south-eastward for about 200 m., dividing the states of Dholpur, Karauli, Jaipur and Jodhpur among themselves. There is no doubt that this irregular line across the central region of India, dividing the Rajputana states from a number of native states in Central India and Gujarat. The most striking physical feature is the Aravalli range of mountains, which intersects the country almost at right angles. About three-fifths of Rajputana lies north-west of the range, leaving two-fifths on the east and south. The tract lying to the north-west contains the states of Bikainar, Jaisalmer and Jodhpur. With the exception of these three only the hill-ranges mediate below the Aravalli, this divisa is sandy, ill-watered and unproductive, improving gradually from a desert in the north-west and west to comparatively fertile land on the east. The country divides into the eastern and south-east of the Aravalli affords a striking contrast to the sandy plains on the north-west of the range, and is blessed with fertile lands, hill-ranges and long stretches of forest, where fuel and fodder are abundant.

The main rivers are the Luni, the Chambal and the Banas. The first of these, the only river of any consequence in the north-western division, flows for 200 m. from the Pushkar valley, close to Ajmere, to the Rung of Chutch. In the southern division the river the river is longer and, being more fertile. The Chambal, by far the largest river in Rajputana, through which it flows for about one-third of its course, while it forms its boundary for another third. The source of the river is in the highlands of the Vindhyas, approximately 200 ft. above the sea; it soon becomes a considerable stream, collecting in its course the waters of other rivers, and finally discharging itself into the Jumna after a course of 560 m. Next in importance ranks the Banas, which rises in the south-west near Kankroli in Udaipur. It collects nearly all the drainage of the Udaipur plateau with that of the eastern slopes and hill-tracts of the Aravalli, and joins the Chambal a little beyond the north-eastern extremity of the Bundi state, after a course of about 300 m. Other rivers, which wash the feet of the Sabarmati, which rise among the south-west hills of Udaipur and take a south-west course. The river Mahi, which passes through the states of Partabgarh and Banswara, receiving the Som, drains the south-west corner of Rajputana. Although the Aravalli states possesses no natural freshwater lakes, there are several important artificial lakes, all of which have been constructed with the object of storing water. The only basin of any extent is the Sambhar salt lake of about 50 m. in circuit.

Geology.—Geologically considered, the country may be divided into three regions—a central, and the largest, comprising the whole width of the Aravalli system, formed of very old sub-metamorphic rocks; and a western, and smaller, which is subdivided, along which the most ancient formations are abruptly replaced by the great basin of the Vindhyana strata, or are overlaid by the still more extensive spread of the Deccan trap, forming the plateau of Malwa; and a western region, of very ill-defined margin, in which, besides some rocks of undetermined age, it is more or less known or suspected that Tertiary and Secondary strata stretch across from Sind, beneath the sands of the desert, towards the flanks of the Aravallis. Rajputana produces a variety of metals. Ore of cobalt is obtained in no other locality in India, and although zinc blende has been found elsewhere it is known to have been extracted only in this province. Copper and lead are found in several parts of the Aravalli range, as well as the copper mines at Jaisalmer, Shallik, and iron ores abound in several states. Alum and blue vitriol (sulphate of copper) are manufactured from decomposed schists at Khetri in Shalikwati. Good building materials are plentiful. Thus the country abounds with the grey slate of the Rains limestone (a fine-grained crystalline marble) and the Jaislamar limestone stand pre-eminent.

Climate.—The climate throughout Rajputana is very dry and hot. When the monsoon is blowing the winds are much colder in the north than in the lower districts, with hard frost and ice on the Bikainar borders. The rainfall is very unequally distributed: in the western part, which comes near to the limits of the rainless plains of Asia, it is very scanty, and scarcely averages more than 3 in. in the south-west the fall is more copious, sometimes exceeding 100 in. at Abu; but, except in the south-west highlands of the Aravallis, rain is most abundant in the south-east. Notwithstanding all its drawbacks, Rajputana is reckoned one of the healthiest countries in India, at least for the native inhabitants.

Population.—In 1901 the population was 9,723,301, showing a decrease of 26% in the decade owing to the great famines of 1897-1898 and 1900-1901. The greatest mortality was caused by virulent malarial fever, which raged during the autumn months of 1900 and the early months of 1901. Epidemics of cholera, which occurred during the years of scarcity and famine, also swept away large numbers.

It is commonly supposed that, because nearly the whole country is ruled by Rajputs, therefore the population consists mainly of Rajputs, but these are merely the dominant race, and the territory is called Rajputana because it is politically possessed by Rajputs. The whole number of this race is 620,229, and nowhere do they form a majority of the whole population in a state; but they are strongest, numerically, in the northern states and in Udaipur. By rigid precedence the Brahman occupy the first rank; they are numerous and influential, and with them may be classed the peculiar and important caste of Bhats, the keepers of secular tradition and of the genealogies. Next come the mercantile castes, mostly belonging to the Jain sect; these are followed by the powerful cultivating tribes, such as the Jats and Gujars, and then come the so-called aboriginal tribes, chief of whom are the Minas, Bhils and Meos. Rajasthani is the chief language of the country, one of the older of the dialects being spoken by 7,035,593 persons, more than 20% of the population. The average gross revenue of all the states is estimated at £2 millions sterling.

The mass of the people are occupied in agriculture. In the large towns banking and commerce flourish to a degree beyond what might be expected. In the north the staple products for export are salt, grain, wool and cotton, in the south opium and cotton; while the imports consist of sugar, hardware and piece goods. Rajputana is very poor in industrial production. The principal manufactures are cotton and woollen goods, carvings in ivory and working in metals, &c., all of which handicrafts are chiefly carried on in the eastern states. The system of agriculture is
very simple; in the country west of the Aravallis only one crop is raised in the year, while in other parts south and east of the Aravallis two crops are raised annually, and various kinds of cereals, pulses and fibres are grown. In the desert tracts fine breeds of camels, cattle, horses and sheep are to be found wherever there is pasture. Irrigation, mostly from wells, is almost confined to the N. portion. The country is traversed throughout by the Rajputana railway, with its Malwa branch in the south, and diverging to Agra and Delhi in the north. Jodhpur, Udaipur and Bikanir have constructed branch railways at their own cost, the first of which was extended in 1901 to Hyderabad in Sind. In 1909 another line was opened running N. near the E. boundary from Kotah to Bharatpur.

History.—Only faint outlines can be traced of the condition of Rajputana previous to the invasion of Upper India by the Mahommedans, and these indicate that the country was subject for the most part to two or three powerful tribal dynasties. Chief of these were the Rahtors, who ruled at Kanauj; the Chaoshans of Ajmere; the Solankis of Anhilwara, in Gujarat; the Gohls with the Sisodhyas sept, still in Mewar or Udaipur, and the Kachwaha clan, still in Jaipur. These tribal dynasties of Rajputs were gradually supplanted by the Moslem invaders of the 11th century and weakened by internal feuds. At the beginning of the 16th century the Rajput power began to revive, only to be overthrown by Baber at Fatehpur Sikri in 1527. The clans were finally either conquered, overawed or conciliated by Akbar—all except the distant Sisodhyia clan, which, however, submitted to Jehangir in 1616. From Akbar's accession to Aurangzeb's death, a period of 151 years, the Mogul was India's master. Aurangzeb's death and the invasion of Nadir Shah led to a triple alliance among the three leading chiefs, which internal jealousy so weakened that the Maharattas, having been called in by the Rahtors to aid them, took possession of Ajmere about 1756; thenceforward Rajputana became involved in the general disorganization of India. By the end of the century nearly the whole of Rajputana had been virtually subdued by the Maharattas. The victories of Generals Wellesley and Lake, however, saved the Rajputs; but on Lord Wellesley's departure from India the floodgates of anarchy were reopened for ten years. On the outbreak of the Pindari War in 1817 the British government offered its protection. The Pindaris were put down, Amir Khan submitting and signing a treaty which constituted him the first ruler of the existing state of Tonk. By the end of 1818 similar treaties had been executed by the other Rajput states with the paramount power. Sindia gave up the district of Ajmere to the British, and the pressure of the great Maharatta powers upon Rajputana was permanently withdrawn. Since then the political history of Rajputana has been comparatively uneventful. The great storm of the Mutiny of 1857, though dangerous while it lasted, was short. Most of the rajas remained loyal; and the capture of the town of Kotah, which had been held by the mutineers of that state, in March 1858, marked the extinction of armed rebellion. Rajputana is a very beautiful province, having some fine religious buildings in ruins and others in excellent preservation. Among the latter are the mosques at Ajmere and the temples on Abu. But the most characteristic features of architecture in the country are shown in the forts and palaces of the chiefs and in their cenotaphs.

See J. Tod, Annals and Antiquities of Rajastan (1829, 1832); W. W. Webb, Currencies of the Hindu States of Rajputana (1893); Chiefs and Leading Families of Rajputana (1903); and Rajputana Gazetteer (Calcutta, 1908).

RAJSHAHI. a district and division of British India, in the province of Eastern Bengal and Assam. The administrative headquarters are at Rampur Boulia. The area of the district is 2,503 sq. m., comprising an alluvial plain seamed with old river-beds and studded with marshes. The Ganges and the Mahananda are its principal rivers; the former constitutes a great natural boundary-line to the south and south-west, and the latter, which rises in the Himalayas, borders the district on the west for a few miles before joining the Ganges. Other rivers are the Narad and Baral, important offshoots of the Ganges; the Atrai, a channel of the Tista; and the Jamuna, a tributary of the Atrai. Both the Atrai and the Jamuna belong to the Brahmaputra system and are navigable throughout the year for small cargo boats. The drainage of Rajshahi is not carried off by means of its rivers, but through the chains of marshes and swamps, the most important of which is the Chalan bhill or lake, which discharges itself into the Brahmaputra. In 1901 the population was 1,462,407, showing an increase of 1.6% in the decade. Rice is the staple crop, with pulses, oilseeds and jute. Indigo has disappeared. Sericulture has received a stimulus from the efforts of the agricultural department, supported by private enterprise, to improve the breed of silkworms. The hemp grown on a small tract in the north of the district supplies all the ganja that is consumed in Bengal. The district is traversed from south to north by the main line of the Eastern Bengal railway to Darjeeling, with a branch to Bogra. Most of the permanent buildings in the district were severely damaged by the earthquake of the 12th of June 1897. When the East India Company took over the administration of Bengal in 1765, the zamindari of Rajshahi or Nattor was one of the largest and most important in the province. It appears to have extended from Bhagalpur on the west to Dacca on the east, and to have included an important subdivision called Nij-Chakla Rajshahi on the south of the Ganges. The total area was estimated at 13,000 sq. m., or more than five times the size of the present district. Having been found much too large to be effectually administered by one central authority, Rajshahi was stripped in 1793 of a considerable portion of its outlying territory, and a natural boundary-line was drawn to the west, south and east along the Ganges and Brahmaputra. Its north-western limits were reduced in 1873, when the present district of Malda was constituted. The erection of Bogra into a separate jurisdiction in 1821 still further reduced its area, and in 1832 the limits of Rajshahi were fixed by the constitution of Pabna into an independent jurisdiction.

The DIVISION OF RAJSHAHI is coextensive with northern Bengal, from the Ganges to the mountains. It comprises the seven districts of Rajshahi, Dinajpur, Jalpaiguri, Malda, Rangpur, Bogra and Pabna. Total area, 18,091 sq. m. Pop. (1901) 6,130,072.

RAKE (O.E. raec, cognate with Du. raak, Ger. Recken, from a root meaning to scrape together, heap up), an agricultural and horticultural implement consisting of a toothed bar fixed transversely to a handle, and used for the collection of cut hay, grass, &c., and, in gardening, for loosening the soil, light weeding and levelling, and generally for purposes performed in agriculture by the harrow. The teeth of the hand-rake are of wood or iron. For the horse-drawn rake, a bar with long curved steel teeth is mounted on wheels (see Hay and Haymaking). The word "rake" has been used since the 17th century in the sense of a man of a dissolute or dissipated character. This is a shortened form of the earlier "rake-hell," apparently in contrast with the 16th century "rake-hell." In military and naval use, "rake" means to enfilade, to fire so that the shot may pass lengthwise along a ship, a line of soldiers, enervations, &c. In the nautical sense of the projection or slope of a ship's bows or stern or the inclination of a mast, the word is apparently an adaptation of the Scandinavian raka, to reach, in the sense of reach forward.

RÁKÖZCY, the name of a noble Hungarian family, which in the 10th century was settled in the county of Zemplén, and members of which played an important part in the history of Hungary during the 17th century.

George I., prince of Transylvania (1591-1649), who began his career as governor of Onod, was the youngest son of Sigismund Rákóczi (1544-1608), who shared in the insurrection of Stephen Bocskay against the Emperor Rudolph II., and was for a short time prince of Transylvania. In 1616 he married his second wife, the highly gifted zealous Calvinist, Susannah Lorántffy, who exercised a great influence over him. He then took a leading part in the rebellion of Gabriel Bethlen, who
made him commander of Kassa, and was elected prince of Transylvania on the 26th of November 1630 by the diet of Segesvár. He followed the policy of Gabriel Bethlen, based on the maintenance of the political and religious liberties of the Hungarians. His alliance with Gustavus Adolphus of Sweden for that purpose was no secret at Vienna, where the court estimated at their right value Sture's hysterical alarms of pacific amity. On the 2nd of February 1644, at the solicitation of the Swedish and French ambassadors, and with the consent of the Porte, he declared war against the Emperor Ferdinand III. Nearly the whole of imperial Hungary was soon in his hands, and Ferdinand, hardly pressed by the Swedes at the same time, was compelled to conclude (Sept. 16, 1645) with Rákóczy the peace of Linz, which accorded full religious liberty to the Magyars, and ceded to Rákóczy the fortress of Regéc and the Tokaj district. On the death of Wladislaus IV. (1648) Rakoczy aimed at the Polish throne also, but died before he could accomplish his design. His capital, Gyula Fehérvár, was a great Protestant resort and asylum.

George II., prince of Transylvania (1621-1660), was the eldest son of George I. and Susannah Lorántfy. He was elected prince of Transylvania during his father's lifetime (Feb. 19, 1642), and married (Feb. 3, 1643), Sophia Báthory, who was previously compelled by his mother to reject the Roman faith and turn Calvinist. On ascending the throne (Oct. 11, 1648), his first thought was to realize his father's Polish ambitions. With this object in view, he allied himself, in the beginning of 1649, with the Jesuit henchman Bohdan Chmielnicki, and the hussars of Moldsav and Wielopoli. It was not, however, till 1657, as the ally of Gustavus Adolphus, that he led a rabble of 40,000 semi-savages against the Polish king, John Casimir. He took Cracow and entered Warsaw with the Swedes, but the moment his allies withdrew the whole scheme collapsed, and it was only on the most humilitating terms that the Poles finally allowed him to return to Transylvania. Here (Nov. 3, 1657) the diet, at the command of the Porte, deposed him for undertaking an unauthorized war, but in January 1658 he was reinstated by the Medgyes Diet. Again he was deposed by the grand vizier, and again reinstated as if nothing had happened, but all in vain. The Turks again invaded Transylvania, and Rákóczi died at Nagyvárads of the wounds received at the battle of Gyula (May 1660).

See Imre Bethlen, Life and Times of George Rákóczi I. (Hung.) (Nagy-Enved, 1829); Life (Hung.) in Sándor Szilagyi's Hungarian Historical Biographies (Budapest, 1891).

Francis I., prince of Transylvania (1645-1676), was the only son of George Rákóczi II. and Sophia Báthory. He was elected prince of Transylvania during his father's lifetime (Feb. 18, 1652), but lost both crown and father at the same time, and withdrew to the family estates, where, at Patak and Makovica, he kept a splendid court. His mother converted him to Catholicism, and on the 1st of March 1666 he married Helen Zrínyi. In 1670 he was implicated in the Zrínyi-Prangepán conspiracy, and only saved his life by the interposition of the Jesuits on the payment of an enormous ransom.

See Sándor Szilagyi, The Rákóczi Family in the 17th Century (Hung.) (Pest, 1861).

Francis II., prince of Transylvania (1672-1735), was born at Borsi, Zamplény county, on the 27th of March 1676. Having lost his father during infancy, he was educated under the guardianship of his heroic mother, Helen Zrínyi, in an ultrapatriotic Magyar environment, through which he claimed a share in his tutelage. In 1682 his mother wedded Imre Thököly, who took no part in the education of Rákóczi, but used him for his political purposes. Unfortunately his stepfather's speculations suffered shipwreck, and Rákóczi lost the greater part of his estates. It is said that the imperialists robbed him of 1,000,000 florins' worth of plate and supported a whole army corps out of his revenues (1683-85). As a child of twelve he witnessed the heroic defence by his mother of his ancestral castle of Munkács against Count Antonio Caraffa (d. 1693). On its surrender (Jan. 7, 1688) the child was transferred to Vienna that he might be isolated from the Hungarian nation and brought up as an Austrian magistrate. Cardinal Kollonics, the sworn enemy of Magyar separatism, now became his governor, and sent him to the Jesuit college at Neuhaus in Bohemia. In 1690 he completed his course at Prague, and in 1694 he married Maria Amelia of Hesse-Kassel, and lived for the next few years on his Hungarian estates. At this time Rákóczi's birth, rank, wealth and brilliant qualities made him the natural leader of the Magyar nation, and his name was freely used in all the insurrections of the period, though at first he led a life of the utmost circumspection (1667-1700). Hungary was then regarded at Vienna as a conquered realm, whose naturally rebellious inhabitants could only be kept under by force of arms. Kollonics was the supreme ruler of the kingdom, and his motto was "Make of the Magyar first a slave, then a beggar, and then a Catholic." It was a matter of deep regret to the Magyars that a reign of terror and save the national independence by making Hungary independent of Austria as heretofore. Rákóczi and a few other patriotic magnates deeply sympathized with the sufferings of the nation, and on the eve of the war of the Spanish Succession they entered into correspondence with Louis XIV. for assistance through one Longueval, a Belgian general in the Austrian service, who professed to be a friend of the Rákóczyans, who initiated him into all their secrets. Longueval betrayed his trust, and Rákóczi was arrested and imprisoned at Eperjes. His wife saved him from certain death by enabling him to escape to Poland in the uniform of a dragoon officer. On the 18th of June 1703 he openly took up arms against the emperor, most of whose troops were now either on the Rhine or in upper Italy; but, unfortunately, the Magyar gentry stood aloof from the rising and his ill-supported peasant levies (the Kuruczes) were repeatedly scattered. Yet at first he had some success, and on the 26th of September was able to write to Louis XIV. that the whole kingdom up to the Danube was in his power. He also issued his famous manifesto, Recrudescunt virnae inculyae gentis Hungariae, to justify himself in the eyes of Europe. The battle of Blenheim made any direct help from France impossible, and on the 13th of June 1704 his little army of 7000 men was routed by the imperialists at Koronce and subsequently at Nagyszombat. Want of arms, money, native officers and infantry, made, indeed, any permanent success in the open field impossible. Nevertheless, in May 1705, when the Emperor Leopold I. was succeeded by Joseph I., the position of Rákóczi was at least respectable. With the aid of several eminent French officers and engineers he had drilled his army into some degree of efficiency, and had at his disposal 52 horse and 31 foot regiments. Even after the rout of Pudentina (Aug. 11, 1705), he could put 10000 men in the field. In September 1705 he was also able to hold a diet at Szsécény, attended by many nobles and some prelates, to settle the government of the country.

Rákóczi, who had already been elected Prince of Transylvania (July 6, 1704), now surrounded himself with a council of state of 24 members. The religious question caused him especial difficulty. An ardent Catholic himself, nine-tenths of his followers were nevertheless stern Calvinists, and in his efforts to secure them toleration he alienated the pope, who dissuaded Louis XIV. from assisting him. Peace negotiations with the emperor during 1705 came to nothing, because the court of Vienna would not acknowledge the independence of Transylvania, while France refused aid unless the rebels officially till they had formally proclaimed the deposition of the Habsburgs, which last desperate measure was actually accomplished by the Öndor diet on the 13th of June 1707. This was a fatal mistake, for it put an end to any hope of a compromise, and alienated both the emperor's foreign allies and the
RALEIGH, SIR WALTER 869

majority of the Magyar gentry, while from Louis XIV. Rákóczi only got 100,000 thalers, the Golden Fleece, and a promise (never kept) that the Hungarians should be included in the general peace. But into a direct alliance with Rákóczi the French king would not enter, and Laszló Vetési, Rákóczi's envoy at Versailles, in 1708 advised his master to place no further reliance on the French court. Shortly afterwards, at Trensen (Aug. 3, 1708), Rákóczi's army was scattered to the winds. The rout of Trensen was followed by a general abandonment. The remnant of the host, too, was now thoroughly demoralized and dared not face the imperialists. A fresh attempt to renew the war in 1710 was speedily ruined by the disaster of Romhány (Jan. 22), and a desperate effort to secure the help of Peter the Great also failing, Rákóczi gave up everything for lost, and on the 21st of February 1711 quit his country for ever, refusing to accept the general amnesty conceded after the peace of Szatmár (see Hungary, History). He lived for a time in France on the bounty of Louis XIV., finally entering the Carmelité Order. In 1717, with forty comrades, he volunteered to assist the Turks against the Austrians, but on arriving at Constantinople discovered there was nothing for him to do. He lived for the rest of his life at the little town of Rodosti, where he died on the 8th of April 1734. He remains were solemnly transferred to Hungary in 1907 at the expense of the state.

See Autobiography of Prince Francis Rákóczi (Hun.) (Miskolcz, 1903); E. Jurkovich, The Liberation Wars of Prince Francis Rákóczi (Hun.) (Besztercebánya, 1903); S. Endrödi, Kurses Notes, 1700-1720 (Hun.) (Budapest, 1897). (R. N. B.)

RALEIGH, SIR WALTER (c. 1552-1618), British explorer, poet and historian, was born probably in 1552, though the date is not quite certain. His father, Walter Raleigh of Fardell, in the parish of Cornwood, near Plymouth, was a country gentleman of old family, but of reduced estate. Walter Raleigh the elder was three times married. His famous son was the child of his third marriage with Catherine, daughter of Sir Philip Champmorn of Modbury, and widow of Otho Gilbert of Compton. By her first marriage she had three sons, John, Humphrey and Adrian Gilbert. Mr. Rawley has been strongly urged to give up living in his own house of Fardell. His son was born at the farm house of Hayes near the head of Budleigh Salterton Bay, on the coast of Devonshire between Exmouth and Sidmouth. The name is written with a diversity exceptional even in that age. Sir Walter, his father, and a half-brother used different forms. The spelling Raleigh was adopted by Sir Walter's widow, and has been commonly used, though there has been a tendency to prefer "Ralegh" in recent times. It was almost certainly pronounced "Rawley."

In 1568 he was entered as a commoner of Oriel College, Oxford, but he took no degree, and his residence was brief. In 1569 he followed his cousin Henry Champmorn, who took over a body of English volunteers to serve with the French Hugenouts. From a reference in his History of the World it has been supposed that he was present at the battle of Jarnac (13th of March 1569), and it has been asserted that he was in Paris during the Massacre of St. Bartholomew in 1572. Nothing, however, is known with certainty of his life till February 1575, when he was resident in the Temple. During his trial in 1603 he declared that he had never studied the law, but that his breeding had been "wholly gentleman, wholly soldier." In June 1578 his half-brother Sir Humphrey Gilbert obtained a patent for six years authorizing him to take possession of "any remote barbarous and heathen lands not possessed by any Christian prince or people." The gentry of Devon had been much engaged in maritime adventure of a privateering or even piratical character since the reign of Henry VIII. In the reign of Elizabeth they were the leaders in colonial enterprises in conflict with the Spaniards in America. During 1578 Humphrey Gilbert led an expedition which was a piratical venture against the Spaniards, and was driven back after an action with them and the loss of a ship in the Atlantic. Raleigh accompanied his half-brother as captain of the "Falcon," and was perhaps with him in an equally unsuccessful voyage of the following year. Gilbert was impoverished by his ventures, and Raleigh had to seek his fortune about the court. In the course of 1580 he was twice arrested for duels, and he attached himself to the queen's favourite, the earl of Leicester, and to the earl of Oxford, son-in-law of Burghley, for whom he carried a challenge to Sir Philip Sidney. By the end of 1580 he was serving as captain of a company of foot in Munster. He took an active part in suppressing the rebellion of the Desmonds, and in the massacre of the Spanish and Italian adventurers at Smerwick in November. His letters prove that he was the advocate of a ruthless policy against the Irish, and did not hesitate to recommend assassination as a means of getting rid of their leaders.

In December 1581 he was sent home with despatches, as his company had been disbanded on the suppression of the Desmonds. His great fortune dates from his arrival at court where he was already not unknown. Raleigh had been in correspondence with Walsingham for some time. The romantic stories told by Sir Robert Naunton in the Fragmenta Regalia, and by Fuller in his Worthies, represent at least the mythical truth as to his rise into power. It is quite possible that Raleigh, at a time when his court clothes represented "a considerable part of his estate," did (as the old story says) throw his mantle on the ground to help the queen to walk dry-shod over a puddle, and that he scribbled verses with a diamond on a pane of glass to attract her attention, though we only have the gossip of a later generation for our authority. It is certain that his tall and handsome person, his caressing manners and his quick wit pleased the queen. The rewards showered on him were out of all proportion to his services in Ireland, which had not been more distinguished than those of many others. In March 1582 he was granted a reward of £100, and the command of a company, nominally that he might be exercised in the wars, but in reality as a form of pension, since he was allowed to discharge his office by deputy and remained at court. In February 1583 he was included in the escort sent to accompany the duke of Anjou from England to Flanders. In 1583 the queen made him a grant of Durham House in the Strand (London), the property of the see of Durham, which had been used of late as a royal guest-house. In the same year the queen's influence secured him two beneficial leases from All Souls, Oxford, which he sold to his advantage, and a patent to grant licences to "vintners,"—that is, tavern keepers. This he sublet, and when his agent, one Browne, cheated him, he got the grant revoked, and reissued on terms which allowed him to make £100 a year. In 1584 he had a licence for exporting woollen cloths, a lucrative monopoly which made him very unpopular with the merchants. He was knighted in 1584. In 1585 he succeeded the earl of Bedford as Warden of the Stannaries. Raleigh made a good use of the great powers which the wardenship gave him in the mining districts of the west. He reduced the old customs to order, and showed himself fair to the workers. In 1586 he received a grant of 40,000 acres of the forfeited lands of the Desmonds, on the Blackwater in Ireland. He was to plant English settlers, which he endeavoured to do, and he introduced the cultivation of the potato and of tobacco. In 1587 he received a grant in England of part of the forfeited land of the conspirator Babington.

During these years Raleigh was at the height of his favour. It was the policy of Queen Elizabeth to have several favourites at once, lest any one might be supposed to have exclusive influence with her. Raleigh was predominant during the period between the predominance of Leicester and the rise of the earl of Essex, who came to court in 1587. It is to be noted that Elizabeth treated Raleigh exclusively as a court favourite, to be enriched by monopolies and grants at the expense of her subjects, but that she never gave him any great office, nor did she admit him to the council. Even his post of captain of the Guard, given in 1587, though honourable, and, to a man who would take gifts for the use of his influence, lucrative, was mainly ornamental. His many offices and estates did not monopolize the activity of Raleigh. The patent given to his half-brother Sir Humphrey Gilbert was to run out in 1584. To
avert this loss Raleigh, partly out of his own pocket and partly by securing the help of courtiers and capitalists, provided the means for the expedition to Newfoundland in 1583, in which Gilbert, who had been reduced to sell "the clothes off his wife's back" by his previous misfortunes, finally perished. Sir Humphrey's patent was renewed in favour of Sir Walter in March 1584.

Raleigh now began the short series of ventures in colonization which have connected his name with the settlement of Virginia. It has often been said that Raleigh showed a wise originality in his ideas as to colonization. But in truth the patent granted to him, which gave him and his heirs the proprietary right over all territory they occupied subject to payment of one-fifth of the produce of all mines of precious metals to the crown, is drawn closely on Spanish precedents. Nor was there any originality in his desire to settle English colonists, and encourage other industries than mining. The Spaniards had pursued the same aim from the first. In April 1584 Raleigh sent out two captains, Philip Amadas and Arthur Barlowe, on a voyage of exploration. They sailed by the Canaries to Florida, and from thence followed the coast of North America as far as the inlet between Albemarle and Pamlico sounds in the modern state of North Carolina. The name of Virginia was given to a vast and undefined territory, but none of Raleigh’s captains or settlers reached the state of Virginia. In the same year he became member of parliament for Devonshire, and took the precaution to secure a parliamentary confirmation of his grant. His first body of settlers, sent out in 1585 under Sir Richard Grenville, landed on what is now Roanoke Island in North Carolina. Sir R. Grenville showed himself mainly intent on taking prizes, going and coming. The settlers got on bad terms with the natives, deserted, and deserted the colony when Sir Francis Drake visited the coast in 1586. Attempts at colonization at the same place in 1586 and 1587 proved no more successful (see North Carolina), and in 1586 Raleigh, who represented himself as having spent £40,000 on the venture, resigned his rights to a company of merchants, preserving to himself a rent, and a fifth of whatever gold might be discovered.

After 1587 Sir Walter Raleigh was called upon to fight for his place of favour with the earl of Essex (see Essex, 1st Earl of). During the Armada year 1588 he was more or less in eclipse. He was in Ireland for part of the year with Sir R. Grenville, and was employed as vice-admiral of Devon in looking after the coast-defences and militia levy of the county. During this year he received a challenge from Essex which did not lead to an encounter. In 1589 he was again in Ireland. He had already made the acquaintance of Edmund Spenser and now visited him at his house at Kilcolman. It was by Raleigh’s help that Spenser obtained a pension, and royal aid to publish the first three books of the Faerie Queen. The exact cause of Raleigh’s partial disgrace at court is not known, but it was probably due to the queen’s habitual policy of checking any influence arising by the promotion of another. In 1588 he accompanied the expedition to the coast of Portugal, which was intended to cause a revolt against King Philip II., but failed completely. In 1591 he was at the last moment forbidden to take part in the voyage to the Azores, and was replaced by his cousin Sir R. Grenville, whose death in action with the Spaniards was the subject of one of Sir Walter’s most vigorous pieces of prose writing. In 1592 he was again at sea with an expedition to intercept the Spanish trade, but was recalled by the queen. The cause of his recall was the discovery that he had seduced one of her maids of honour, Elizabeth Throgmorton. Raleigh denied in a letter to Robert Cecil that there was any truth in the stories of a marriage between them. On his return he was put into the Tower, and if he was not already married was married there. To placate the queen he made a fantastic display of despair at the loss of her favour. It must be remembered that the maids of honour could not marry without the consent of the queen, which Elizabeth was always most reluctant to give and would be particularly unwilling to give when the husband was an old favourite of her own. Raleigh proved a good husband and his wife was devoted to him through life. As the ships of the expedition had taken a valuable prize, the Portuguese carrack “Madre de Dios,” and as there was a dispute over the booty, he was released to superintend the distribution. He had been a large contributor to the cost of the expedition, but the queen, who sent only two ships, took the bulk of the spoil, leaving him barely enough to cover his expenses.

Raleigh now retired from court to an estate at Sherborne in Dorsetshire, which just before his disgrace he had extorted from the bishop of Salisbury, to whose see it belonged, by a most unscrupulous use of the royal influence. A son was born to him here in 1594, and he kept up a friendly correspondence with Sir Robert Cecil, afterwards earl of Salisbury, the secretary of state. But a life of constant retirement was uncongenial to Raleigh, and as his profuse habits, together with the multiplicity of his interests, had prevented him from making any advantage out of his estates in Ireland, he was embarrased for money. In 1595 he therefore sailed on a voyage of exploration with a view to conquest, on the coast of South America. The object was undoubtedly to find gold mines, and Raleigh had heard the wild stories of El Dorado which had been current among the Spaniards for long. His account of his voyage, The Discoverie of Guiana, published on his return, is the most brilliant of all the Elizabethan narratives of adventure, but contains much manifest romance. It was received with incredulity. He was now the most unpopular man in England, not only among the courtiers, but in the nation, for his greed, arrogance and alleged scepticism in religion. In 1599 he was named with the poet Marlowe and others as an atheist. At court he was not at first received. The share he took in the capture of Cadiz in 1596, where he was seriously wounded, was followed by a restoration of favour at court, and he was apparently reconciled to Essex, whom he accompanied on a voyage to the Azores in 1597. This cooperation led to a renewal of the quarrel, and Raleigh, as the enemy of Essex who was the favourite of the soldiers and the populace, became more unpopular than ever. In 1600 he obtained the governorship of Jersey, and in the following year took a part in suppressing the rebellion of Essex, at whose execution he presided as captain of the Guard. In 1600 he sat as membre for Penzance in the last parliament of Elizabeth’s reign. In parliament he was a steady friend of religious toleration, and a bold critic of the fiscal and agrarian legislation of the time.

The death of the queen and the accession of James I. were ruinous to Raleigh. James, who looked upon Essex as his partisan, had been prejudiced, and Raleigh’s avowed desire for the prolongation of the war with Spain was utterly against the peace policy of the king. Raleigh was embarrassed for money, and had been compelled to sell his Irish estates to Richard Boyle, afterwards 1st earl of Cork, in 1602. He was expelled from Durham House, which was reclaimed by the bishop, from the custody of the Guard, deprived of his monopolies, which the king abolished, and of the government of Jersey. In his anger and despair he unquestionably took some part in the complication of conspiracies which arose in the first months of James’s reign, and was committed to the Tower on the 10th of July 1603. Here he made what appears to have been an insincere attempt to stab himself, but only inflicted a small wound. His trial at Winchester, November 1603, was conducted with such outrageous unfairness as to shock the opinion of the time, and his gallant bearing in face of the brutality of the Attorney-General, Sir Edward Coke, turned public opinion in his favour. It is now impossible to reach the truth, but on the whole it appears probable that Raleigh was cognizant of the conspiracies, though the evidence produced against him was insufficient to prove his guilt. Much was kept back by the council, and the jury was influenced by knowing that the council thought him guilty.

The sentence of death passed on Raleigh, and others tried at about the same time, was in most cases not carried out.
RALEIGH—RALPH 871

Raleigh was sent to the Tower, where he remained till the 19th of March 1616. His estate of Sherborne, which he had transferred to his son, was taken by the king, who availed himself of a technical irregularity in the transfer. A sum of £5,000 offered in compensation was only paid in part. Raleigh's confinement was easy, and he applied himself to chemical experiments and literature. He had been known as one of the most poetical of the minor lyric poets of an age of poetry from his youth. In prison he composed many treatises, and the only volume of his vast History of the World published. He also invented an elixir which appears to have been a very formidable quack stimulant. Hope of release and of a renewal of activity never deserted him, and he strove to reach the ear of the king by appealing to successive ministers and favourites. At last he secured his freedom in a way discreditable to all concerned. He promised the king to find a gold mine in Guiana without trenching on a Spanish possession. It must have been notorious to everybody that this was impossible, and the Spanish ambassador, Gondomar, warned the king that the Spaniards had settlements on the coast. The king, who was in need of money, replied that if Raleigh was guilty of piracy he should be executed on his return. Raleigh gave promises he could not keep, and sailed on the 17th of March 1617, relying on the speed of accidents and the intrigues he had entered into in Savoy and France. The expedition, on which the wreck of his fortune was spent, was ill-appointed and ill-manned. It reached the mouth of the Orinoco on the last day of 1617. Raleigh was ill with fever, and remained at Trinidad. He sent five small vessels up the Orinoco under his most trusted captain, Lawrence Keymis, with whom went his son Walter and a nephew. The expedition found a Spanish settlement on the way to the supposed mine, and a fight ensued in which Sir Walter's son and several Spaniards were killed. After some days of bush fighting with the Spaniards, and of useless search for the mine, Keymis returned to Sir Walter with the news of his son's death and his own utter ruin. Stung by Raleigh's reproach Keymis killed himself, and then after a miserable scene of recriminations, hesitations and mutiny, the expedition returned home. Raleigh was arrested, and in pursuance of the king's promise to Gondomar was executed under his old sentence on the 29th of October 1618. During his confinement he was occupied in preparing pamphlets and other devices, but when he knew his end to be inevitable he died with serenity and dignity. His wife survived him, and he left a son, Carew Raleigh. His enmity to Spain made him a popular hero.

AUTHORITIES.—An edition of his Works in eight volumes was published in London in 1829. It contains a Life by Oldys and Birch, written with all the knowledge then available. A Life of Sir Walter Raleigh (London, 1806, 2nd ed.) was much used by Southey in his biography of Sir Walter Raleigh in vol. iv. of The British Admirals in the Cabinet Cyclopaedia (London, 1837). Two biographies appeared simultaneously, Life of Sir Walter Raleigh by J. A. Saint John, and Life of Sir Walter Raleigh by E. Edwards (London, 1868). Mr. Edwards's work is in two volumes, of which the second contains the correspondence, and is still the best authority. Smaller lives, which in some cases contain new matter, are those by E. W. Gosse, "Raleigh" in English Worthies (1886); W. Stetson, "Raleigh" in American National Cyclopedia (1905); and Sir Walter Raleigh (London 1897); and H. de Selincourt, Great Raleigh (1908). For special episodes see Sir John Pope Hennessy, Sir Walter Raleigh in Ireland (London, 1883), and T. N. Brushfield, Sir Walter Raleigh (London, 1890). Sir Walter's relations with Elizabeth and her court are detailed by Misses Overton and Osborn. Raleigh's poems have been published, Poems, with biography and critical introduction by Sir F. Brydges (London, 1813), and Poems of Raleigh with those of Sir H. Wotton, &c., edited by J. Hannah (London, 1892). S. R. Gardiner made a careful examination of the events of Raleigh's life, and the Accession and the Accession of Charles I. to the Outbreak of the Civil War (1883-84).

RALEIGH, the capital of North Carolina, U.S.A., and the county-seat of Wake county, about 145 m. N. by W. of Wilmington. Pop. (1890) 12,678; (1900) 13,643, of whom 5721 were negroes; (1910, census) 10,218. Area 4 sq. m. It is served by the Southern, the Seaboard Air Line, the Raleigh & Southport, and the Norfolk Southern railways. The city lies about 360 ft. above sea-level on ground sloping gently in all directions from its centre, where there is a beautiful park of 4 acres known as Union Square, in which is the State Capitol and from which extend four broad streets. On the western border of the city is Pullen Park (about 40 acres), including the campus of the College of Agriculture and Mechanic Arts; it was named in honour of the donor, R. Stanhope Pullen, who was also a benefactor of the college. The State Capitol (1849) is surmounted by a dome and modelled to some extent after the Parthenon and other buildings of ancient Greece; the first Capitol (begun in 1794) was burned in 1831. In the vicinity are the Governor's Mansion, the Supreme Court Building, the State Library, the building of the State Department of Agriculture, housing the State Museum (of geology, mineralogy, agriculture and horticulture, botany, zoology, ethnology, &c.), and the Post Office. Elsewhere are the County Court House, the State Hospital for the Insane (1850), founded through the efforts of Dorotha Lynde Dix, situated on Dix Hill and having in connexion with it a colony for epileptics; a state school for white blind, deaf and dumb (1843), and a state institute for negro deaf mute and blinds (1867); the state penitentiary (with a department for the criminal insane); a National Cemetery and a Confederate Cemetery; a Methodist Orphanage (1900) and a Roman Catholic Orphanage, the St Luke's Home for old ladies (1855); under the King's Daughters, a State (Confederate) Hospital (1864) and a State (Rex) public hospital (1909). Raleigh is the seat of the North Carolina College of Agriculture and Mechanic Arts (1889), in connexion with which is an agricultural experiment station; of three schools for girls—Peace Institute (Presbyterian, 1837), St Mary's School (Protestant Episcopal, 1842) and Meredith College (Baptist, 1891); of the medical department of the University of North Carolina; and of two schools for negroes—Shaw University (Baptist, 1865), with 530 students in 1906-1909, and St Augustine's School (Protestant Episcopal, 1868), a training school, with 466 students in 1906-1909. In 1908 the State Library (founded 1841) contained 39,000 volumes, the Supreme Court Library (founded 1870) about 17,000 volumes and the Olivia Raney public library (founded 1901) 9250 volumes. The city is the see of a Protestant Episcopal bishop. The principal industrial interests are trade in leaf tobacco and cotton raised in the vicinity, and the manufacture of cotton goods, phosphate fertilizers, foundry and machine-shop products, wooden-ware, &c. The Seaboard Air Line and the Raleigh & Southern Railways are the two chief methods of transportation. In 1905 the factory product was valued at $1,086,671. 14.7: more than in 1900. Electric power is conveyed to the city from Buckhorn Falls, on the Cape Fear river, about 26 m. south of Raleigh, and from Milburnie on the Neuse river, 6 m. distant.

In 1788 the site of the city, then known as Wake Court House, was chosen for the capital of the state; and in 1792 the city was laid out and named in honour of Sir Walter Raleigh. In 1794 the state legislature met here for the first time. Raleigh was incorporated in 1795 and was reincorporated in 1803; its present charter dates from 1809. General William T. Sherman's army, on its march through the Carolinas, passed through the city on the 13th of April 1865. Raleigh was the birthplace of President Andrew Johnson; the house in which he was born has been removed to Pullen Park. By an extension of its boundaries the city nearly doubled its area and increased its population in 1907.

RALPH (d. 1122), archbishop of Canterbury, called Ralph Turbine, or Ralph d'Escures from his father's estate of Escures near Noyon, held the abbey of St Martin at Séez in 1079, and ten years later became a monk of this house. Soon afterwards he paid a visit to England, where his half-brother, Seffrid Pelochin, was bishop of Chichester, and in 1100 he took refuge in England from the violence of Robert of Belesme, passing some time with his friends St Anselm and Gundulf. In March 1108 he succeeded Gundulf as bishop of Rochester. After Anselm's death in April 1109 Ralph acted as administrator of the see of Canterbury until April 1114, when he himself was chosen archbishop at Windsor. In this capacity he was very assertive of the rights of the archbishop of Canter-
RALPH DE GUADER—RAMBAUD

bury and of the liberties of the English church. He claimed authority in Wales and Scotland, and he refused to consecrate Thurstan as archbishop of York because the latter prelate declined to profess obedience to the archbishop of Canterbury. This step involved him in a quarrel with the Papacy, and he visited Rome, but was unable to obtain an interview with pope Paschal II., who had left the city. In spite of peremptory orders from Paschal’s successors, Gelasius II. and Calixtus II., the archbishop still refused to consecrate Thurstan, and the dispute was unsettled when he died on the 20th of October 1122.

RALPH DE GUADER, earl of Norfolk (fl. 1070), was the son of a Norman who had held high positions in East Anglia, perhaps that of earl, in the reign of Edward the Confessor (c. 1055). His son Ralph fought on the Norman side at Hastings, and was made earl of Norfolk by William the Conqueror. In 1075 the king’s refusal to sanction his marriage with the sister of Roger, earl of Hereford, caused the two ears to revolt. They were easily defeated, though Ralph sent for Denmark for aid and went there himself to fetch them. Ralph forfeited his English lands, and took refuge in Brittany on his wife’s estate. In 1076, having plotted against Duke Hoel of Brittany, he was besieged at Dol, and the Conqueror came to Hoel’s aid; but Ralph finally made his peace. Both he and his wife took part in the first crusade (1099), and died on the road to Palestine.

RALPH OF COGGESHALL (d. after 1227), English chronicler, was at first a monk and afterwards sixth abbot (1207-1218) of Coggeshall, an Essex foundation of the Cistercian order. Ralph himself tells us these facts; and that his resignation of the abbacy was made against the wishes of the brethren, in consequence of his bad health. He took up and continued a Chronicon Anglicanum belonging to his house; the original work begins at 1066, his own share at 1187. He hoped to reach the year 1227, but his autograph copy breaks off three years earlier. Ralph makes no pretensions to be a literary artist. Where he had a written authority before him he was content to reproduce even the phraseology of his original. At other times he strings together in chronological order, without any links of connexion, the anecdotes which he gathered from chance visitors. Unlike “Benedictus” and Roger of Hoveden, he makes little use of documents; only three letters are quoted in his work. On the other hand, the corrections and erasures of the autograph show that he took pains to verify his details; and his informants are sometimes worthy of exceptional confidence. Thus he vouches Richard’s chaplain Anselm for the story of the king’s capture by Leopold of Austria. The tone of the chronicle is usually impassionate; but the original text contained some personal strictures upon Prince John, which are reproduced in Coggeshall’s work. The admiration with which Ralph regarded Henry II. is attested by his edition of Ralph Niger’s chronicle; here, under the year 1161, he replies to the in-temperate criticisms of the original author. On Richard I. the abbot passes a judicious verdict, admitting the great qualities of that king, but arguing that his character degenerated. Towards John alone Ralph is uniformly hostile; as a Cistercian and an adherent of the Mandeville family he could hardly be otherwise. Ralph refers in the Chronicon (s.a. 1001) to a book of visions and miracles which he had compiled, but this is no longer extant. He also wrote a continuation of Niger’s chronicle, extending from 1162 to 1175 (printed in R. Anstruther’s edition of Niger, London, 1851), and short annals from 1066 to 1233.

The autograph manuscript of the Chronicon Anglicanum is to be found in the British Museum, on Cotton, Vespasian D. XII. The first volume contains the continuation of Ralph Niger. The Chronicon Terrae Sanctae, formerly attributed to Ralph, is by another hand; it was among the sources on which he drew (for the Chronicon Anglicanum is greatly indebted to mail les merveils anglo-saxonnes sub reg. Johanne [printed by Martene and Durand, Ampl. Collectio, vi. pp. 877-882] is merely an excerpt from the Chronicon Anglicanum. This latter work was edited for the Rolls series in 1875 by J. Stevenson.

RAM, PIERRE FRANÇOIS XAVIER DE (1804-1863), Belgian churchman and historian, was born at Louvain in 1804. He took orders early, and was appointed professor of poetry at the seminary of Malines, and archivist of the diocese. During the years immediately before the revolution of 1830, Ram, who was much influenced by Lamennais, was active in bringing about a coalition of Liberals and Catholics against the Dutch government established by the Powers on the fall of Napoleon, and in endeavouring to give a democratic character to the policy of his church. He declined to stand as a member of the Belgian assembly, and applied himself wholly to teaching and to editing or composing historical books. As professor of philosophy at Malines he succeeded in bringing about the foundation of the Catholic university, which was transferred to Louvain in 1834. He was rector of the university till his death in 1865.

The first known of his publications is the Documents relatifs aux troubles du pays de Liége 1455-1505, published by the Commission royale de l’Histoire de Belgique (Brussels, 1844). A Notice sur la vie et les travaux de Mgr P. F. X. de Ram, by J. J. Thonissen, will be found in the Annuaire de l’Académie royale de Belgique (Brussels, 1866).

RAM, a male sheep, one kept for breeding purposes in domestication and not castrated, as opposed to the castrated "wether" (see SNEEP). For the ram as one of the signs of the zodiac, see RAM. The word is connected with O.Norse rám, strong, or with Sansk. rám, to sport. The butting propensities of the ram have given rise to the many transferred senses of the word, chief and earliest of which is that of a battering implement used before the days of cannon for beating in the gates and breaking the walls of fortified places (see BATTERING RAM). Many technical uses of the term have been developed from this, e.g. the weight of a pile-driving machine, the piston of a hydraulic press and other machines or portions of machines worked by water power (see HYDRAULICS). The ancient war-vessels were fitted with a beam (Lat. rostrum, Gr. θόδωρον), projecting from the bows, and used to ram or crush in the sides of an opposing vessel; for the development of this in the modern battleship, see SNIP.

RAMADAN, the month of the Mahommedan year in which absolute fasting from dawn to sunset is required. The law is laid down in Koran ii. 179-184, and is as follows: A fast had always been a part of religion. In Islam it was to fall in this month because in it the Koran was revealed, and it was holier than the others. It was to begin when the new moon was actually seen, and last until sight of the next new moon; to extend each day from the time when a white thread could be distinguished from a black one and until nightfall; to be absolute in that time as to food, drink, women. The daytime should be passed, by preference, in retreat (i. tikaf) in the mosque in pious exercises; during the night all otherwise lawful things to be lawful. The sick and those on a journey might be excused, but should fast thereafter an equivalent number of days. Unexcused breaking of the fast might be atoned for by feeding of the poor. The last ten days of the month are regarded as especially sacred; these Mahomet himself used to pass in retreat. In the course of them falls the "Night of Decree," or "of Power" (Koran xc. 1), but its exact date is not known. On it intercourse between heaven and earth is peculiarly open, and many wonders take place. Fasting in Ramadán is reckoned one of the five pillars, or absolute requirements, of Islam. It is followed by the Lesser Festival, the first three days of the month Shawwal (see BAIRAM). Naturally, during it all the activities of life are reduced to a minimum, and those who can afford it turn night into day as much as possible.

RAMBAUD, ALFRED NICOLAS (1842-1905), French historian, was born at Besançon on the 2nd of July 1842. After studying at the École normale supérieure, he completed his studies in Germany. He was one of that band of young scholars, among whom were also Ernest Lavisse, Gabriel Monod and Gaston Paris, whose enthusiasm was aroused by
the principles and organization of scientific study as applied beyond the Rhine, and who were ready to devote themselves to their cherished plan of remodelling higher education in France. He was appointed "répétiteur" at the École des Hautes Études on its foundation in 1868. His researches were at that time directed towards the Byzantine period of the middle ages, and to this period were devoted the two theses which he composed for his doctorate in letters, De byzantino hippodromo et circensibus factionibus (revised in French for the Revue des Deux Mondes, under the title of "Le monde byzantin; le sport et l'hippodrome," 1871), and L'Empire grec au Xe siècle, Constantin Porphyrogénète (1870). This latter work is still accepted as a good authority, and caused Rambaud to be hailed as a master on the Byzantine period; but with the exception of one article on Digenis Akritas, in the Revue des Deux Mondes (1875), and one other on Michael Psellos, in the Revue historique (vol. iii., 1879), Rambaud’s researches were diverted towards other parts of the East. The Franco-German War inspired him with the idea for some courses of lectures which developed into books: La domination française en Allemagne; les Français sur le Rhin, 1792-1804 (1873) and L'Allemagne sous Napoléon I, 1804-1811 (1874). He watched attentively the rôle played by Russia, and soon observed how much to the interest of France, a good entente with this power would be. He accordingly threw himself into the study of Russian history, staying in Russia in order to learn its language, institutions and customs. On his return, he published La Russie épique, a study of the heroic songs (1876), a short but excellent Histoire de la Russie depuis les origines jusqu'à l'année 1877 (1878; 5th ed., 1900), Français et Russes, Moscou et Sébastopol 1812-1854 (1876; 2nd ed., 1881), and finally the two important volumes on Russian diplomatic history in the Recueil des Instructions données aux ambassadeurs (vols. vii. and ix., 1890 and 1891). He was not improbably moved by considerations of foreign policy to publish a book on some of the most studied nations of Europe. This popular work, though based on solid research. After teaching history in the Faculties of Arts at Caen (1871) and Nancy (1873), he was called to the Sorbonne (1883), where he was the first to occupy the chair of contemporary history. By this time he had already entered into politics; he had been chef du cabinet of Jules Ferry (1879-1881), though this did not distract him from his literary work. It was under these conditions that he composed his Histoire de la civilisation française (2 vols., 1885, 1887; 4th ed., 1901) and his Histoire de la civilisation contemporaine en France (1888; new ed., entirely revised, 1906), and undertook the general editorship of the Histoire générale du IVe siècle jusqu'à nos jours. The plan of this great work had been drawn up with the aid of Ernest Lavisse, but the entire supervision of its execution was carried out by Rambaud. He contributed to it himself some interesting chapters on the history of the East, of which he had a thorough knowledge. In 1883 Rambaud published, in collaboration with J. B. Baillie, a French translation of J. R. Seeley’s Expansion of England, and in the preface he laid great emphasis on the enormous increase of power brought to England by the possession of her colonies, seeing in this a lesson for France. He was anxious to see the rise of a “Greater France," on the model of “Greater Britain,” and it was with this idea that he undertook to present to the public a series of essays, written by famous explorers or political men, under the title of La France coloniale, histoire, géographie, commerce (1886; 6th ed., 1893). Having become senator for the department of Doubs (1893-1902), Rambaud held the position of minister of Public Instruction from 1896 to 1898, and in that capacity endeavoured to carry on the educational work of Jules Ferry, to whose memory he always remained faithful. He dedicated to his former chief a book (Jules Ferry, 1903), which is a valuable testimony to the efforts made by France to organize public education and found a colonial empire; but this fidelity also won him some enemies, who succeeded for some time in preventing him from becoming a member of the Institute. He was finally elected a member of the Académie des Sciences morales et politiques on the 11th of December 1897, in place of the Duc d'Uxelles, of whose life he wrote an accurate life (xxii., 2nd series, of the Mémoires of this academy). His many interests ended by wearing out even his robust constitution, and he died at Paris on the 10th of November 1905.

Rambert, Eugène (1830–1886), Swiss author, was born at Säles near Swiss Clarens on the 6th of April 1830, the eldest son of a Vaudois schoolmaster, from whom he received his education. When in 1845 his father lost his post, owing to the religious disputes, Rambert became a teacher in Paris, and later a tutor in England and at Geneva. When the affairs of the family improved, Rambert was able to pursue his studies for the ministry, but he was more attracted by literature, and in 1845 became professor of French literature at the academy of Lausanne, and in 1860 at the Federal polytechnic school at Zürich; where he remained till 1881, when he again became professor at Lausanne. His principal work, Les Alpes suisses (5 vols., 1866-1875; republished with large additions, according to his own scheme, in 6 vols., 1887-1886), is a mine of miscellaneous information on the subject. He also published several volumes of poetry, as well as a volume entitled Écrivains nationaux (1874, republished 1889), and biographies of the poet Vinet (1875), of the poet Juste Olivier (1879) and of the artist Alexandre Calame (1883). He died on the 21st of November 1886.

Rambert’s Dernières Poésies were edited (1903) by Henri Warnery, whose Eugène Rambert (Lausanne, 1890) contains a critical estimate.

(R. A. B. C.)

Rambouillet, Catherine de Vivonne, Marquise de (1588–1665), a lady famous in the literary history of France, was born in 1588. She was the daughter and heiress of Jean de Vivonne, marquis of Pisani, and her mother Giulia was of the noble house of Savelli. She was married, when but fifty years old, to Charles d’Angennes, viscount of Le Mans, and afterwards marquis of Rambouillet. The young marquise found the coarseness and intrigue that then reigned in the French court little to her taste, and after the birth of her eldest daughter, Julie d’Angennes, in 1607, she began to gather round her the circle afterwards so famous. She established herself at the Hôtel Pisani, called later the Hôtel de Rambouillet, the site of which is close to the Grands Magasins du Louvre. Mme de Rambouillet took great trouble to arrange her house for purposes of reception, and devised suites of small rooms where visitors could move easily, and could find more privacy than in the large reception rooms of the ordinary house. The hôtel was rebuilt on these lines in 1618. It maintained its importance as a social and literary centre until 1650. Almost all the more remarkable personages in French society and French literature frequented it, especially during the second quarter of the century, when it was the fashion that all was beautiful to the marquise. The history of the Rambouillet salon is the key to Mme de Rambouillet’s beauty, though no portrait of her is known to exist. Her success as a hostess was due to many causes. Her natural abilities had been carefully trained, but were not extraordinary. Many people were, however, like herself, disgusted with the intrigues at court, and found the comparative austerity of the Hôtel de Rambouillet a welcome change. The marquise had genuine kindness and a lack of prejudice that enabled her to entertain on the same footing princes and princesses of the blood royal, and men of letters, while among her intimate friends was the beautiful Angélique Paulet. The respect paid to ability in her salon effected a great advancement in the position of French men of letters. Moreover, the almost uniform excellence of the memoirs and letters of 17th-century Frenchmen and Frenchwomen may be traced largely to the development of conversation as a fine art at the Hôtel Rambouillet, and the consequent establishment of a standard of clear and adequate expression. Mme de Rambouillet was known as the "incomparable Archétype," the name being an anagram for Catherine, devised by Malherbe and Racan.
Among the more noteworthy incidents in the story of the Hôtel are the sonnet war between the Uranistes and the Jobjistes—partisans of two famous sonnets by Voiture and Benserade—and the composition by all the famous poets of the day of the Guirlande de Julie, a collection of poems on different flowers, addressed in 1643 to Julie d'Angennes, afterwards duchesse de Montausier. Julie herself was responsible for a good deal of the preciseness for which the Hôtel was later ridiculed. Charles de Sainte Maure, who became in 1664 duc de Montausier, had been wooing her for seven years when he conceived the idea of the famous garland, and she kept him waiting for four years more.

The Préciennes, who are usually associated with Molière's avowed caricatures and with the extravagances of Mlle. de Scudéry, but whose name, it must be remembered, Madame de Sévigné herself was proud to bear—insisted on a ceremonious gallantry from their suitors and friends, though it seems from the account given by Tallemant des Réaux that practical jokes of a mild kind were by no means excluded from the Hôtel de Rambouillet. They especially favoured an elaborate and quintescent kind of colloquial and literary expression, imitated from Marini and Gongora, and then fashionable throughout Europe. The immortal Préciennes ridicules of Molière was no doubt directly levelled not at the Hôtel de Rambouillet itself, but at the numerous coteries which in the course of years had sprung up in imitation of it. But the satire did in truth touch the originators as well as the imitators,—the former more closely perhaps than they perceived. The Hôtel de Rambouillet continued open till the death of its mistress, on the 2nd of December 1665, but the troubles of the Fronde diminished its influence.

The chief original authorities respecting Madame de Rambouillet and her set are Tallemant des Réaux in his Histoires, and Antoine Baudeau de Somaine in his Grand Dictionnaire des Préciennes (1690). Many modern writers have treated the subject, notably Victor Cousin, La Société française au xviie siècle (2 vols., 1856), and C. L. Livet, Préciennes et Préciennes . . . (1859). There is an admirable edition (1875) of the Guirlande de Julie by O. Uzanne.

**Rambouillet**, a town of northern France, capital of an arrondissement in the department of Seine-et-Oise, 30 m. S.W. of Paris on the railway to Chartres. Pop. (1906) town, 3065; commune, 6165. Rambouillet derives its whole interest from the associations connected with the ancient château, dating originally from the 14th century, but often rebuilt. A great machicolated tower is all that remains of the medieval building; some apartments with good woodwork are also of interest. The château is surrounded by a beautiful park of 3000 acres and by an extensive forest. The gardens, partly in French, partly in English style, are picturesque, and have an avenue of Louisiana cypress unique in Europe. The park contains the national sheep-farm, where in the 18th century the first flock of merino sheep in France was raised, a school of sheep-farming, and, close to the latter, a small dairy built by Louis XVI. The shooting of the famous coverts of Rambouillet is reserved for the presidents of the Republic. The town is the seat of a sub-prefecture and has a tribunal of first instance and a preparatory infantry school. Trade is in grain, wool, flour and wood. Watch-springs are manufactured.

Originally a royal domain, the lands of Rambouillet passed in the 14th century to the D'Angennes family, who held them for three hundred years and built the château. Francis I. died there in 1547, and Charles IX. and Catherine de Médicis found a refuge there in the Wars of Religion, as Henry III. did after them. The title became a marquisate in 1612, at which time it was held by Charles d'Angennes, husband of Catherine de Vivonne (q.v.), the famous marchioness of Rambouillet. Created a duchy and peerage in favour of the duke of Toulouse, son of Louis XIV., Rambouillet was subsequently bought and embellished by Louis XV., who erected a model farm and other buildings. The place was a hunting-seat of Napoleon I. and Charles X., and it was here that in 1830 the latter signed his abdication.

**Rameau, Jean Philippe** (1683–1764), French musical theorist and composer, was born at Dijon on the 23rd of October 1683. His musical education, partly in consequence of his father's desire that he should study law, still more through his own wayward disposition, was of a desultory character. In 1705 his father sent him to Milan to break off a foolish love-match. But he learned little in Italy, and soon returned, in company with a wandering theatrical manager, for whom he played the second violin. He next settled in Paris, where he published his Premier livre de pièces de clavecin, in 1706. In 1717 he made an attempt to obtain the appointment of organist at the church of St Paul. Deeply annoyed at his unexpected failure, he retired for a time to Lille, whence, however, he soon removed to Clermont-Ferrand. Here he succeeded his brother Claude as organist at the cathedral.

Burning with desire to remedy the imperfections of his early education, Rameau diligently studied the writings of Zarlin, Descartes, Messené, F. Kircher and other theorists. He not only mastered their views but succeeded in demonstrating their weak points and substituting for them a system of his own. His keen insight into the constitution of certain chords, which in early life he had studied only by ear, enabled him to propound a series of hypotheses, many of which are now accepted as established facts. While the older contrapuntists were perfectly satisfied with the laws which regulated the melodious involutions of their vocal and instrumental parts, Rameau demonstrated the possibility of building up a natural harmony upon a fundamental bass, and of using that harmony as an authority for the enactment of whatever laws might be considered necessary for the guidance either of the contrapuntist or the less ambitious general composer. And in this he first explained the distinction between two styles, which have been called the "horizontal and vertical systems," the "horizontal system" being that by which the older contrapuntists regulated the onward motion of their several parts, and the "vertical system" that which constructs an entire passage out of a single harmony. From fundamental harmonies he passed to inverted chords, to which he was the first to call attention; and the value of this discovery fully compensates for his erroneous theory concerning the chords of the eleventh and the great (Angl. "added") sixth (see *Harmony*).

Rameau first set forth his new theory in his Traité de l'harmonie (Paris, 1722), and followed it up in his Nouveau système (1726), Génération harmonique (1737), Démonstration (1750) and Nouvelles réflexions (1752). But it was not only as a theorist that he became famous. Returning to Paris in 1722 he first attracted attention by composing some light dramatic pieces, and then showed his real powers in his opera, Hippolyte et Aricie, founded on Racine's Phèdre and produced at the Académie in 1733. Though this work was violently opposed by the admirers of Lulli, whose party spirit eventually stirred up the famous "guerre des boufons," Rameau's genius was too brilliant to be trampled under foot by an ephemeral faction and his ultimate triumph was assured. He afterwards produced more than twenty operas, the most successful of which were Dardanus, Castor et Pollux, Les Indes galantes and La princesse de Navarre. Honours were showered upon him. He was appointed conductor at the Opéra Comique, and the directors of the opera granted him a pension. King Louis XVI. appointed him composer to the court in 1745, and in 1754 honoured him with a patent of nobility and the order of St Michael. But these last privileges were granted only on the eve of his death at Paris on the 12th of September 1764.

See the biographies in Charles Poissot (1864), Nisard (1867), Pougin (1876).

**Rameses**, or **Rameses** (Gen. xlvi. 11; Exod. xili. 37; Num. xxxiii. 3), or, with a slight change in the vowel points, **Rameses** (Exod. i. 11), the name of a district and town in Lower Egypt, is notable as affording the mainstay of the current theory that King Rameses II. was the pharaoh of the oppression and his successor Minephthah the pharaoh of the exodus. The actual facts, however, hardly justify so large an inference. The
first three passages cited above are all by the priestly (post-exile) author and go together. Jacob is settled by his son Joseph in the land of Rameses, and the same Rameses the exodus naturally takes place. The older narrative speaks not of the land of Rameses but of the land of Goshen. It is therefore probable, therefore, that the later author interprets this passage to suit his own times, just as the Septuagint in Gen. xlv. 25 names of Goshen Heropolis and the land of Rameses. Heroopolis lay on the canal connecting the Nile and the Red Sea, and not far from the head of the latter, so that the land of Rameses must have been near Wadi Tumilat near the line of the modern fresh-water channel. In Exod. i. 11, again, the store-cities or arsenals which the Hebrews built for Pharaoh are specified as Pithom and Raamses, to which the Septuagint adds Heliopolis. Pithom also takes us to the Wadi Tumilat. But the Israelites maintain a continuous recollection of the names of the cities on which they were forced to build, or were these names rather added by a writer who knew what fortified places were in his own time to be seen in Wadi Tumilat? The latter is far the more likely case, when we consider that the old form of the story of the Hebrews in Egypt is throughout deficient in precise geographical data, as might be expected in a history not committed to writing till the Israelites had resided for centuries in another and distant land. The post-exilic priestly author indeed gives a detailed route for the exodus (which is lacking in the older story), but he, we know, was a student of geography, and might have turned to what he could gather from traders as to the caravan routes. And at all events to argue that, because the Hebrews worked at a city named after Rameses, they did so in the reign of the founder, is false reasoning, for the Hebrew expression might equally be used of repairs or new works of any kind.

It appears, however, from remains and inscriptions that Rameses II. did build in Wadi Tumilat, especially at Tell Maskhūta, which Lepsius therefore identified with the Raamses of Exodus. This identification is commemorated in the name of the adjacent railway station. But Naville's excavations found that the ruins were those of Pithom and that Pithom was identical with the later Heroopolis. Petrie found sculptures of the age of Rameses II. at Tel Rotab, in the Wadi Tumilat west of Pithom, and concludes that this was Rameses. The Biblical city is probably one of those named Prameses, "House of Rameses," in the Egyptian texts. See Pithom; and W. M. F. Petrie, Hyksos and Israelite Cities, p. 28 et seq. (W. R. S., F. L. G.)

RAMESWARAM, a town of British India, in the Madura district of Madras, on the island of Pamban in Palk Straits. It contains one of the most venerable Hindu shrines, founded, according to tradition, by Rama himself, which for centuries has been the resort of thousands of pilgrims from all parts of India. The great temple, with its pillared corridors 700 ft. long, is perhaps the finest example of Dravidian architecture.

RAMIE (RHEA, CHINA-GRASS), the product of one or more species of the genus Boehmeria, a member of the order Urticaeae and nearly allied to the stinging nettle genus (Urtica), from which, however, it differs in absence of stinging hairs. Some confusion has arisen in the use of the various terms Chinggrass, Ramie and Rhea. Two plants are concerned. One, Boehmeria nivea, China-grass, has been cultivated by the Chinese from very early times under the name Tschu-ma. The other, probably a variety of the same species (Boehmeria nivea, var. tenacissima), though sometimes regarded as a distinct species (B. tenacissima), is the Ramie (Malay zami) of the Malay Islands and the Rhea of Assam.

Boehmeria nivea is a shrubby plant with the growth of the common nettle but without stinging hairs, sending up each season a number of straight shoots from a perennial underground rootstock. The long-stalked leaves recall those of the nettle in their shape and serrated margin, but their backs are

1 From the position of the words it is even not unlikely that "Pithom and Raamses" may be the addition of a redactor, and that the first author of Exod. i. 11 only spoke generally of store-cities.
said to crack and break easily when sharply bent, and on account of their hairy character are not the same smart appearance as those made from flax. Although the fibre is in some cases 12 in. long, it varies considerably in length. This is one of the drawbacks in the preparing and spinning. It is impossible to make perfect yarns from fibres of various lengths; hence it is necessary either to separate the fibres into reasonable groups, or to cut them into satisfactory lengths. The latter method appears, on the whole, to be the better, and it is the method adopted by Messrs Greenwood & Batley Limited, Leeds, who make special machinery for the dressing, preparing and spinning of ramie and China-grass. If no special machinery be employed, the length of the fibre will decide the class of machinery to be used. The fibre has been prepared and spun on flax, wool and silk-waste machinery, but it must be understood that none of these systems are really suitable for the process. A fibre with special characteristics requires special machinery for its manufacture.

When so many different opinions obtain as to which existing machinery is best adapted for the preparing and spinning of ramie, it is not surprising to find that divers methods are employed in the process of manufacture. In general, however, we may say that, after decortication, the first process is that of degumming. This is usually done by immersing the fibre in a caustic soda solution, which is then drained. The fibre is laid on galvanized trays, of which as many as forty-four can be fitted in a cage, which is then placed inside the boiling kett, the lid of which is screwed down and the necessary pressure of steam admitted. After having been boiled, the fibre is removed from the kett, washed in water, immersed in the alkali neutralized, and the fibre thoroughly washed to remove all traces of chemicals. The bulk of the water is removed by a hydro-extractor, and the fibre is then hung up or laid on perforated plates at dry.

To facilitate the subsequent processes, the fibre is softened by passing it through a machine fitted with fluted rollers. Then follow the operations of dressing, roving, wet spinning and doubling, and finally the twisted thread is passed rapidly through a gas flame in order to remove the superfluous hairs. In spite of many disappointments which have been experienced in connexion with the treatment of this fibre, we are of the opinion that it will ultimately hold a good place amongst commercial fibres. It is at present spun in several European countries, but its use is still very limited. This is due, not to any imperfection of the fibre, but to its price and to the limited supply of raw material. It is at present chiefly used for gauze mantles, for which it is particularly well adapted. It has also been used for paper-kraft, for lining of underwear, and for canvas and several other fabrics. If only a good supply of clean fibre could be obtained, there is not the least doubt that manufacturers and machine-makers would quickly provide means for dealing with it. (T. B. B.)

RAMILLIES, a village of Belgium, in the province of Brabant, 13 miles N. by E. of Namur, between the sources of the Little Gheete and of the Mehaigne. It is famous for the victory of the Allies under the duke of Marlborough over the French commanded by Marshal Villeroi on the 12th/23rd of May 1706. The position of the French on the high ground about Ramillies was marked by the villages of Autreglise (Anderluc) on the left, Offuz on the left centre, Ramillies on the right centre and Taviers on the right close to the river Mehaigne. In front of the last was a smaller village, Franquenay, which was held as an advanced post. Between these points d'appui the ground was mostly open upland, and where the whole was a defective in so far that the villages were barely within cannon-shot of each other. It was particularly strong on the flanks, which were protected by the marshy beds of the Mehaigne and the Little Gheete. Ramillies stands almost on the watershed of these adjacent valleys, and here Marlborough decided to deliver his main attack. The forces were about equal, and were at first equally distributed along the whole line of either party. Marlborough's local concentration of force at the spot where the attack was to be pressed home was made not before, but after the action had opened (cf. Neerwinden). Villeroi's left wing of cavalry and infantry was secure—and at the same time imitating the manoeuvres of the little Gheete, and the French commander allowed himself to be imposed upon by a demonstration in this quarter, convinced perhaps by the presence of the British contingent that a serious attack was intended. The morning was spent in arraying the lines of battle, and it was about 1.30 when the cannonade opened. Soon the first lines of infantry of the Allied centre and left (Dutch) opened the attacks on Franquenay and Taviers and on Ramillies, and, when after a severe struggle Taviers fell into the hands of the Dutch, their commander, Marshal Overkirk, led forward the whole of the left wing cavalry and fiercely engaged the French cavalry opposed to it. The ground was open, both parties had placed the greater part of their horse on this side, and it was only after a severe and prolonged engagement (in which Marlborough himself took part like a trooper and was unhorsed) that the Allies were definitely victorious, thanks to the arrival of a force of cavalry brought over from the Allied right wing. Meanwhile the principal attack on Ramillies had been successfully pressed home, the necessary concentration of force being secured by secretly and skillfully withdrawing some British battalions from the right wing. While Villeroi was trying to bring up supports from the left to take part in the cavalry battle, the French in Ramillies were driven out into the open, where the Allied cavalry, having now gained the upper hand, rode down many battalions. Most of the French cavalry from the other wing, having to force its way through the baggage trains of the army (these had been placed too near the fighting lines), arrived too late, and once Ramillies had fallen the whole line of the Allies gradually took up the offensive. It was not long before the French line was rolled up from right to left, and the retreat of the French was only effectuated in considerable confusion. Then followed for once a relentless pursuit, carried on by the British cavalry (which had scarcely been engaged) to Louvain, 20 m. from the field of battle. Marlborough's unequalled tactical skill and judgment thus sufficed not merely to win the battle, but to win it with so large a margin of force unexpended that the fruits of his victory could be gathered. The French army lost, in killed, wounded and missing, some 15,000 men, the Allies (amongst whom the Dutch had borne the brunt of the fighting) scarcely one-third as many.

RAMLER, KARL WILHELM (1725-1768), German poet, was born at Kolberg on the 29th of February 1725. After completing his studies in Halle, he went to Berlin, where, in 1748, he was appointed professor of logic and literature at the cadet school. In 1746 he became associated with the author, Johann Jakob Engel, in the management of the royal theatre, of which, after resigning his professorship, he became (1790-96) sole director. He died at Berlin on the 11th of April 1768. Ramler was a skilful but cold and uninspired versifier; and the reputation he enjoys as poet and critic is mainly due to his skill in imitating and reproducing in German, classical (mostly Horatian) metrical forms; and he had a reputation, not unfounded, of correcting his friends' writings out of recognition. His Tod Jesu, a cantata, is well known owing to its musical setting by Karl Heinrich Graun.

Ramler published Geistliche Cantaten (1760) and Oden (1767). A collection of his works was published by L. F. G. von Göckingk in Berlin in 1801. He published Geschichte seiner biographischen Skizze Ramlers (1796); and K. Schüttelkopf, Karl Wilhelm Ramler, bis zu seiner Verbindung mit Lessing (1886).

RAMMELSBERG, KARL FRIEDRICH AUGUST (1813-1899), German mineralogist, was born at Ramberg on the 1st of April 1813. He was educated for the medical profession and graduated in 1837 at Berlin University. In 1841 he became privatdozent in the university, and in 1845 professor extraordinary of chemistry. This post he relinquished in 1851 to take the chair of chemistry and mineralogy at the Royal Industrial Institute. In 1874 he was appointed professor of inorganic chemistry, and director of the second chemical laboratory at Berlin. Distinguished for his researches on mineralogy, crystallography and analytical chemistry, he laboured also at metallurgy, and yet found time for a series of important textbooks, in which his learning and sound judgment were combined with a lucid and accurate statement of facts. He was author of Handwörterbuch des chemischen Teiles der Mineralogie (2 vols., 1841; suppl. 1843-53); Lehrbuch der chemischen
Metallurgie (1850); Handbuch der Krystallographischen Chemie (1855); Handbuch der Krystallographisch-physikalischen Chemie (2 vols., 1881–82), some of the earlier works being incorporated in later and more comprehensive volumes with different titles. He died at Gross Lichterfelde, near Berlin, on the 28th of December 1890.

RAM MOHAN ROY (1774–1833), Indian religious reformer, and founder of the Brahma Samaj (q.v.) or Theistic Church, was born at Radhanagar, in the district of Hugli, Bengal, on May 1774. He was the son of a small landowner, and in his early life acquired a knowledge of Persian, Arabic and Sanskrit, besides his own vernacular, Bengali. At the age of sixteen he first assailed idolatry in his Bengali work, entitled The Idolatrous Religious System of the Hindus. This gave offence to his orthodox father, and Ram Mohan left home and spent some years in travel. At the age of twenty-two he began his study of the English language, and he also acquired a knowledge of other modern and ancient European languages. On the death of his father he obtained an appointment under the British government in 1800, from which he retired in 1814, settled down in Calcutta, and devoted himself to religious reform. He had already in 1800 składted a circle for discussing the absurdities of idol worship, and published a striking book in Persian called Tuhfat-al-Muwahhidin ("A Gift to Monotheists"). On his settlement in Calcutta he established a little friendly society (Atmiya Sabha), which met weekly to read the Hindu scriptures and chant monotheistic hymns. In 1820 he issued a collection from the Christian Gospels entitled The Precepts of Jesus the Guide to Peace and Happiness. He also wrote Bengali works on the Vedanta philosophy, translated some of the Upanishads, entered into controversies with Christian missionaries, and on the 23rd of January 1830 definitely established the Brahmo Samaj "for the worship and adoration of the Eternal, Unsearchable, Immutable Being who is the Author and Preserver of the Universe." He gave his support to the governor-general, Lord William Bentinck, for the abolition of the sutil rite, i.e. the custom of permitting Hindu widows to burn themselves on the funeral pyre of their husbands. He also worked hard to spread education among his fellow-countrymen, and to improve the quality and the prestige of the native press. In 1830 the emperor bestowed on him the title of Papabili, and sent him to England as his agent. Raja Ram Mohan Roy gave his evidence before the Select Committee of the House of Commons on the judicial and revenue systems of India. He presented petitions to the House of Commons in support of the abolition of the sutil rite, and had the satisfaction of being present in the House when the appeal against such abolition was rejected on the 11th of July 1832. As the first educated and eminent Indian who had come to England, he received a cordial welcome from learned men; and Bentinck addressed him as an "intensely admired and dearly beloved collaborator in the service of mankind." Ram Mohan also visited France and contemplated a voyage to America, but a sudden attack of brain fever led to his death on the 27th of September 1833. He was buried at Bristol, where a tomb was erected by his friend Dwarka Nath Tagore.

RAMNAD, a town of British India, in the Madura district of Madras, at the base of the spit of land that projects towards the island of Pamban in Palk Strait. Pop. (1901) 14,546. It is the residence of a rajah of the native head of the Marathi race, whose title is setapath, or lord of Adam's Bridge. The estate covers an area of 2104 sq. m., and pays a permanent land revenue of £25,000. It is a desolate and generally unfertile tract, traversed by the South Indian railway.

RAMNICU SARAT (Rămnicu Sărat), the capital of the department of Rămnicu Sarat, Romania; on the railway from Bucuz to Focsani, and on the left bank of the Rămnicu, a tributary of the Sereth. Pop. (1900) 13,134, about 1500 being Jews. The town rises from a marshy plain, east of the Carpathians, and west of the cornlands of southern Moldavia. Salt and petroleum are worked in the mountains, and there is a considerable trade in agricultural produce and preserved meat. Rămnicu Sarat was the scene of battles between the Moldavians and the Walachians in 1434 and 1573, and between the Walachians and Turks in 1654. Here also, in 1789, an Austro-Russian army defeated the Turks. In 1854 the town was almost destroyed by fire and was rebuilt.

RAMNICU VÁLCEA (Rămnicu Vânăta), or Rymnik, an episcopal city and the capital of the department of Vâlcea, Rumania; situated at the foot of the Carpathians, on the right bank of the river Olc, and on the railway from Caracal to Hermannstadt in Transylvania. Pop. (1900) 7317. Three monasteries in the Vâlcea department, those of Bistritza, Cozia and Horezu, are among the finest in Walachia. Besides wine, fruit, grain and timber, the surrounding uplands yield petroleum and salt. Within a few miles are the thermal springs of Olănești and the salt mines of Oenele Mari. The city is said to be the ancient Castra Tralana, and many traces of old encampments bear evidence of this.

RAMPOLLA, COUNT MARIANO DEL TINDARO (1843– ), Italian cardinal, was born on the 17th of August 1843, at Polizzi, in the Sicilian diocese of Cefalu. Having taken his philosophical and theological studies at the College of Ecclesiastical Nobles, and in 1875 was appointed councillor to the papal nunciature at Madrid. Two years later he was recalled to Rome and appointed secretary of the Propaganda for Eastern Affairs, and for Extraordinary Ecclesiastical Affairs. Consecrated titular archbishop of Heraclea in 1885, he returned to Madrid as nuncio, but was shortly afterwards created cardinal and appointed to the papal secretariat of state. New to the Sacred College and free from traditional preconceptions, he was admirably fitted to carry out the papal policy under Leo XIII. (see PAPACY). Rightly or wrongly, he was held personally responsible for the rapprochement with France and Russia and the opposition to the Powers of the Triple Alliance; and this attitude had its effect on his career when Leo XIII. died. Rampolla was undoubtedly the favourite among the papabili cardinals; but the voto of Austria was interposed (see CONCLAVE), and the votes of the Sacred College fell to Cardinal Sarto, who on the 4th of August 1903 became pope as Pius X. Cardinal Rampolla at once resigned the secretary of state, being succeeded by Cardinal Merry del Val, and ceased to play any conspicuous part in the Curia.

RAMPUR, a native state of India, in subdivision to the United Provinces. It lies in Rohilkhand, between the British districts of Moradabad and Fatehpur. Area, 893 sq. m. The country is level and generally fertile; being watered in the north by the rivers Kosila and Nahul, and in the south by the Ramganga. The chief crops are maize, rice and sugar cane. Pop. (1901) 333,212, showing a decrease of 3.3% in the decade. Estimated revenue, £2,344,000; military force, 2,356 men, including two squadrons of Imperial Service lancers. The chief, whose title is nawab, is a Rohilla Pathan, representing the family which established their power over this part of the country in the 18th century. When the Rohillas were subjugated by the nawab of Oudh, with the assistance of a force lent by Warren Hastings, one of their number, Faiq-ulah Khan, from whom the present nawab traces his descent, was permitted to retain possession of Rampur. During the Mutiny of 1857 the nawab of Rampur rendered important services to the British, for which he received a grant of land assessed at £4000 in perpetuity, besides other honours. The state is crossed by the main line of the Oudh & Rohilkhand railway from Bareilly to Moradabad. The town of Rampur is on the left bank of the river Kosila, 620 ft. above the sea, with a railway station 39 m. N.W. of Bareilly. Pop. (1901) 78,758. There are manufactures of damask, pottery, sword-blades and sugar. It is partially, and was once completely, surrounded by a broad bamboo hedge, which formed a strong defence. In addition to a modern fort and several fine buildings, it contains an Arabic college, which attracts students from all parts of India. There are two other towns in India called Rampur, one
of which, the capital of the state of Bashahr in the Punjab, has given its name to the fine woollen shawls, widely known as Rampur chadors.

**RAMPUR BOALIA, or BULLEAH, a town of British India, the administrative headquarters of Rajshahi district in Eastern Bengal and Assam; on the left bank of the Ganges. Pop. (1901) 21,589. It was originally chosen as a commercial factory for the silk trade, which is again being officially encouraged by the agricultural department. The town contains a government college, and an industrial school for sericulture. Most of the public buildings were severely damaged by the earthquake of the 12th of June 1897. There is a daily steamer service on the Ganges.**

**Ramsay, Allan** (1686–1758), Scottish poet, was born at Leadhills, Lanarkshire, on the 15th of October 1686. He was educated at the parish school of Crawford, and in 1701 was apprenticed to a wig-maker in Edinburgh. He married Christian Ross in 1712; a few years after he had established himself as a wig-maker (not as a barber, as has been often said) in the High Street, and soon found himself in comfortable circumstances. His first efforts in verse-making were inspired by the meetings of the Eas y Club (founded in 1712), of which he was an original member, and in 1723 he became a member of the Club. In the society of the members he assumed the name of "Isaac Bickerstaff," and later of "Gawin Douglas," the latter partly in memory of his maternal grandfather Douglas of Muthill (Perthshire), and partly to give point to his boast that he was a "poet sprung from a Douglas loin." The choice of the two names has some significance, when we consider his later literary life as the associate of the Queen Anne poets and as a collector of old Scots poetry. By 1718 he had made some reputation as a writer of occasional verse, which he published in broadsheets, and then (or a year earlier) he turned bookseller in the premises where he had hitherto plied his craft of wig-making. In 1716 he had published a rough transcript of Christie's Kirk on the Green from the Bannatyne MS., with some additions of his own. In 1718 he republished the piece with more supplementary verses. In the following year he printed a collection of Scots Songs. The success of these ventures prompted him to collect his poems in 1722. The volume was issued by subscription, and brought in the sum of four hundred guineas. Four years later he was admitted to the neighbouring Luckenbooths, where he opened a circulating library (the first in Scotland) and extended his business as a bookseller. Between the publication of the collected edition of his poems and his settling down in the Luckenbooths, he had published a few shorter poems and had issued the first instalments of The Tea-Table Miscellany and The Ever Green (both 1724–1727). The Tea-Table Miscellany is "A Collection of Choice Songs Scots and English," containing some of Ramsay's own, some by his friends, several well-known ballads and songs, and some Caroline verse. Its title was suggested by the programme of the Spectator: and the compiler claimed the place for his songs "e'en while the tea's fill'd reeking round," which Addison sought for his speculations at the hour set apart "for tea and bread and butter." In The Ever Green, being a Collection of Scots Poems wrote by the Ingenious before 1600, Ramsay had another purpose, to reawaken an interest in the older national literature. Nearly all the pieces were taken from the Bannatyne MS., though they are by no means verbatim copies. They made his version of Christie's Kirk (published in 1722, and a remarkable pastiche by the editor entitled The Vision. While engaged on these two series, he produced, in 1725, his dramatic pastoral The Gentle Shepherd. In the volume of poems published in 1722 Ramsay had shown his bent to this genre, especially in "Patie and Roger," which supplies two of the dramatic personages to his greater work. The success of the drama was remarkable. It passed through several editions, and was performed at the theatre in Edinburgh; its title is still known in every corner of Scotland, even if it be no longer read. Ramsay wrote little afterwards, though he published a few shorter poems, and new editions of his earlier work. A complete edition of his Poems appeared in London in 1731 and in Dublin in 1733. With a touch of vanity he expressed the fear lest the coolness of fancy that attends advanced years should make me risk the reputation I had acquired." He was already on terms of intimacy with the leading men of letters in Scotland and England. He corresponded with Hamilton of Bangour (q.v.), Somerville (q.v.), Gay (q.v.) and Pope. Gay visited him in Edinburgh, and Pope praised his pastoral—compliments which were undoubtedly responsible for some of Ramsay's unhappy poetic ventures beyond his Scots vernacular. The poet had for many years been a warm supporter of the stage. Some of his prologues and epilogues were written for the London theatres. In 1736 he set about the erection of a new theatre, "at vast expense," in Carrubber's Close, Edinburgh; but the opposition was too strong, and the new house was closed in 1737. In 1755 he retired from his shop to the house on the slope of the Castle Rock, still known as Ramsay Lodge. In this house, called by his friends "the goose-pie," because of its octagonal shape, the poet died on the 7th of January 1758.

Ramsay's importance in literary history is twofold. As a pastoral writer ("in some respects the best in the world," according to Dr. John Gay) he contributed at an early stage to the naturalistic reaction of the 18th century. His Gentle Shepherd, by its directness of expression and its appreciation of country life, anticipates the attitude of the school which broke with neo-classical tradition. It has the "mixed" faults which make the greater poem of his Scots successor, Thomson, a "transitional" document, but these give it an historical, if not an individual, interest. His chief place is, however, as an editor. He is the connecting-link between the greater "Makars" of the 15th and 16th centuries, and Ferguson (q.v.) and Burns. He revived the interest in vernacular literature, and directly inspired the genius of his greater successors. The preface to his Ever Green is a protest against "imported trimming" and "foreign embroidery in our writings," and a plea for a return to simple Scottish tradition. He had no scholarly interest in the past, and he never hesitated to transform the texts when he could give contemporary "point" to a poem; but his instinct was good, and he did much to stimulate an ignorant public to fresh enjoyment. In this respect, too, he was the forerunner of the vast admiration for the Scotch ballads, which followed securely on the publication of Percy's Reliques.

The Tea-Table Miscellany was reprinted in 1871 (2 vols., Glasgow; John Crum); The Ever Green in 1875 (2 vols., Glasgow; Robert Forrester); The Poems of Allan Ramsay in 1877 (2 vols., Paisley; Alex. Gardner). These volumes are uniform in size and binding, though issued by different publishers, and a selection of Ramsay's Poems appeared in 1887 (1 vol. 16mo, London; Walter Scott). There are many popular reprints of The Gentle Shepherd. (G. G. S.)

**Ramsay, Allan** (1713–1754), Scotch portrait-painter, the eldest son of the author of The Gentle Shepherd, was born at Edinburgh in 1713. Ramsay manifested an aptitude for art from an early period, and at the age of twenty we find him in London studying under the Swedish painter Hans Huyssing, and at the St. Martin's Lane Academy; and in 1736 he left for Rome, where he worked for three years under Solimena and Imperiali (Fernandi). On his return he settled in Edin-burgh; and, having attracted attention by his head of Forbes of Culloden and his full-length of the duke of Argyll, he removed to London, where he was patronized by the duke of Bridgewater. He painted many leading worthies, and, though not less than his artistic skill, contributed to render him popular. In 1759 he was appointed to succeed Shakelton as principal painter to the king; and so fully employed was he on the royal portraits which the king was in the habit of presenting to ambassadors and colonial governors, that he was forced to take advantage of the services of a host of assistants—of whom David Martin and Philip Reinagle are the best known. His life in London was varied by frequent visits to Italy, where he occupied himself more in literary and antiquarian research than with art. But this prosperous career came to an end, his health being shattered by an accidental dislocation of the
right arm. With unflinching pertinacity he struggled till he had completed a likeness of the king upon which he was engaged at the time, and then started for his beloved Italy, leaving behind him a series of fifty royal portraits to be completed by his assistant Reinaige. For several years he lingered in the south, his constitution finally broken. He died at Dover on the 10th of August 1784.

Among his most satisfactory productions are some of his earlier ones, such as the full-length of the duke of Argyll, and the numerous bust-portraits of Scottish gentlemen and their ladies which he executed before settling in London. They are full of both grace and individuality; the features show excellent draughtsmanship; and the flesh-painting is firm and sound in method, though frequently tending a little to hardness and opacity. His full-length of Mary Coke is remarkable for the skill and delicacy with which the white satin drapery is managed; while in the portrait of his brown-eyed wife, the eldest daughter of Sir Alexander Lindsay of Evelick, in the Scottish National Gallery, we have a sweetness and tenderness which shows the painter at his highest. This last-named work shows the influence of French art, an influence which helped greatly to form the practice of Ramsay, and which is even more clearly visible in the large collection of his sketches, which the possession of the Royal Scottish Academy and the Board of Education are anxious to acquire.

RAMSAY, SIR ANDREW CROMBIE (1814-1891), British geologist, was born at Glasgow on the 31st of January 1814, being the son of William Ramsay, manufacturing chemist. He was for a time actually engaged in business, but from spending his holidays in Arran he became interested in the study of the rocks of that island, and was thus led to acquire the rudiments of geology. A geological model of Arran, made by him on the scale of two inches to the mile, was exhibited at the meeting of the British Association at Glasgow in 1840, and attracted the notice of Sir R. L. Murchison, with the result that he received from De la Beche an appointment on the Geological Survey, on which he served for forty years, from 1841 to 1881. He was first stationed at Tenby, and to that circumstance may be attributed the fact that so much of his geological work dealt with Wales. His first book, The Geology of the Isle of Arran, was published in 1841. In 1845 he became local director for Great Britain, but he continued to carry on a certain amount of field-work until 1854. To the first volume of the Memoirs of the Geological Survey (1846) he contributed a now classic essay, "On the Denudation of South Uist and the Adobe Clays of England," in which he advocated the theory of the sea forming great plains of denudation, although at the time he underestimated the influence of subaerial agents in sculpturing the scenery. In 1866 he published The Geology of North Wales (vol. iii. of the Memoirs), of which a second edition was published in 1881. He was chosen professor of geology at University College, London, in 1848, and afterwards lecturer in the same subject at the School of Mines in 1851. Eleven years later he was elected to the presidential chair of the Geological Society, and in 1872 he succeeded Murchison as director-general of the Geological Survey. In 1880 he acted as president of the British Association at Swansea, and in the following year retired from the public service, receiving at the same time the honour of knighthood. In 1886 he published a little book entitled The Old Glaciers of Switzerland and North Wales. The study of this subject led him to discuss the Glacial Origin of Certain Lakes in Switzerland, the Black Forest, &c. He dealt also with the origin of The Red Rocks of England (1871) and The River Courses of England and Wales (1872). He particularly devoted much attention to the physical configuration of a district, and he devoted much attention to the effects produced by ice, his name being identified with the hypothesis, which, however, has never commanded general assent, that in some cases lake basins have been scooped out by glaciers. A master in the broader questions of stratigraphy and physical geology, he was a clear exponent of facts, but rather impatient of details, while his original and often bold theories, expressed both in lectures and in writings, stirred others with enthusiasm and undoubtedly exercised great influence on the progress of geology. His lectures to working men, given in 1863 in the Museum of Practical Geology, formed the nucleus of his famous Physical Geology and Geography of Great Britain (5th ed., 1878; 6th ed., by H. B. Woodward, 1894). He received a Royal medal in 1880 from the Royal Society, of which he became a fellow in 1862; he was also the recipient of the Neill prize of the Royal Society of Edinburgh in 1866, and of the Wollaston medal of the Geological Society of London in 1871. He died at Beaumaris on the 9th of December 1891.

See Memoir, by Sir A. Geikie, 1895.

RAMSAY, ANDREW MICHAEL (1668-1743), French writer, of Scottish birth, commonly called the "Chevalier Ramsay," was born at Ayr on the 9th of January 1668. Ramsay served with the English auxiliaries in the Netherlands, and in 1710 visited Fénelon, who converted him to Roman Catholicism. He remained in France until 1724, when he was sent to Rome as tutor to the Stuart princes, Charles Edward and Henry, the future cardinal of York. He was driven by intrigue from this post, and returned to Paris. He was in England in 1730, and received an honorary degree from the University of Oxford. The claim was nominally his discipleship to Fénelon, but in reality beyond his control. He died at St Germain-en-Laye (Seine-et-Oise) on the 6th of May 1743. Ramsay's principal work was Les voyages de Cyrus (London, 1728; Paris, 1727), a book composed in avowed imitation of Télémaque. He also edited Télémaque itself (Paris, 2 vols., 1717) with an introduction, and wrote a Histoire de la vie et des ouvrages de Fénelon (The Hague, 1723), besides a partial biography (Paris, 1735) of Turenne, some poems (Edinburgh, 1728) in English, and other miscellaneous works.

RAMSAY, DAVID (1749-1815), American physician and historian, the son of an Irish emigrant, was born in Lancaster county, Pennsylvania, on the 2nd of April 1749. He graduated at Princeton in 1765, and M.B. at the University of Pennsylvania in 1773, and then settled as a physician at Charleston, South Carolina, where he had a large practice. During the War of Independence he served as a field-surgeon (1780-1781), and from 1776 to 1783 he was a member of the South Carolina legislature. Having acted as one of the "council of safety" at Charleston, he was, on the capture of that City in 1783, seized by the British as a hostage, and for nearly a year was kept in a dungeon at Augusta. From 1782 to 1786 he served in the Continental Congress, and from 1801 to 1815 in the state Senate, of which he was long president. In 1785 he published in two volumes History of the Revolution of South Carolina, in 1789 in two volumes History of the American Revolution, in 1807 a Life of Washington, and in 1809 in two volumes a History of South Carolina. He was also the author of several minor works. He died at Charleston on the 8th of May 1815 from a wound inflicted by a lunatic. His History of the United States in 3 vols. was published posthumously in 1816-1817, and forms the first three volumes of his Universal History Americanized, published in 12 vols. in 1819.

RAMSAY, ROBERT (1842-1882), Australian statesman, was a native of Hawick, Roxburghshire, but his parents emigrated to Victoria when he was a child of four, and he was educated at the Scottish college in Melbourne. He studied law at Melbourne University, and subsequently became a member of a well-known firm of solicitors in the city. He married in 1868 Isabella Catherine Urquhart, and in 1870 entered the assembly for East Victoria in the Conservative and free trade interest. He was a member of the government of James Goodall Francis in 1872-74. He was subsequently postmaster-general (1874-75) in the administration of George Biscoe Kerferd; he held the same office in conjunction with the ministry of education (1875-77) under Sir James M'Culloch; and for a short term in 1880 he was chief secretary and minister of education in the first administration of James Scull. He died on the 23rd of May 1882.
RAMSAY, SIR W. (1852–1919). British chemist. He was born at Glasgow on the 2nd of October 1852. From 1866 to 1870 he studied in his native city, and then went to work under R. Fittig at Tübingen. Returning to Glasgow in 1872 he became assistant in the Young laboratory of technical chemistry at Anderson’s College, and from 1874 acted as tutorial assistant in chemistry at the university. In 1880 he was appointed to the chair of chemistry at University College, Bristol, becoming principal in the following year, and in 1887 he succeeded A. W. Williamson as professor of chemistry at University College, London. His earlier work was mainly concerned with organic chemistry, and he published researches on picoline and its derivatives in 1876–78 and on quinine and its decomposition products in 1878–79. Later his attention was taken up with questions of physical and inorganic chemistry. With Sydney Young and others he investigated the critical state and properties of liquids and the relationship between their vapour pressures and temperature, and with John Shields he applied measurements of the surface tension of liquids to the determination of their molecular complexity. In 1894 he was associated with Lord Rayleigh in the discovery of argon, announced at that year’s meeting of the British Association in Oxford, and in the following year he found in certain rare minerals such as clevite the gas helium which till that time had only been known on spectroscopic evidence as existing in the sun. In 1898 his work with Morris William Travers (b. 1872, who from 1894 had assisted him at University College, London, and in 1903 was appointed professor of chemistry at University College, Bristol, enabled him to announce the existence in the atmosphere of three new gases, neon, krypton and xenon. Turning to the study of radioactivity, he noticed its association with the minerals which yield helium, and in support of the hypothesis that that gas is a disintegration-product of radium he proved in 1903 that it is continuously formed by the latter substance in quantities sufficiently great to be directly recognizable in the spectroscope. Among the books written by Sir William Ramsay, who was created K.C.B. in 1902, are A System of Chemistry, 1891, The Gases of the Atmosphere, 1896, and Modern Chemistry, vol. i. Theoretical, vol. ii. Systematic, 1901, and he edited a series of “Textbooks of Physical Chemistry.”

RAMSAY, SIR WILLIAM MITCHELL (1851–1919). British archaeologist. He was born on the 15th of March 1851. He was educated at the universities of Aberdeen, Oxford and Göttingen, and was a fellow of Exeter College, Oxford (1878–80), and Lincoln College (1885; honorary 1899). In 1885 he was elected professor of classical archaeology at Edinburgh, and in the next year professor of humanity at Aberdeen. From 1886 onwards he travelled widely in Asia Minor and rapidly became the recognized authority on all matters relating to the districts associated with St Paul’s missionary journeys and on Christianity in the early Roman Empire. He received the honorary degrees of D.C.L. Oxford, LL.D. St Andrews and Glasgow, D.D. Edinburgh, and was knighted in 1906. He was elected a member of learned societies in Europe and America, and has been awarded medals by the Royal Geographical Society, the Royal Scottish Geographical Society and the University of Pennsylvania. His numerous publications include: The Historical Geography of Asia Minor (1890); The Church in the Roman Empire (1893); The Cities and Bishops of Phrygia (2 vols., 1895, 1897); St Paul the Traveller and the Roman Citizen (1895; Germ. trans., 1908); Impressions of Turkey (1897); Was Christ born at Bethlehem? (1898); Historical Commentary on Galatians (1899); The Education of Christ (1902); The Letters to the Seven Churches of Asia (1905); Pauline and other Studies in Early Christian History (1906); Studies in the History and Art of the Eastern Provinces of the Roman Empire (1906); The Cities of St Paul (1907); Lu-Can and Pauline Studies (1908); The Thousand and One Churches (with Miss Gertrude L. Bell, 1909); and articles in learned periodicals and the 9th, 10th and 11th editions of the Encyclopædia Britannica. His wife, Lady Ramsay, granddaughter of Dr Andrew Marshall of Kirkintilloch, accompanied him in many of his journeys and is the author of Everyday Life in Turkey (1897) and The Romance of Elizavet (1899).

RAMSBOTTOM, an urban district in the Heywood parliamentary division of Lancashire, England, 4 m. N. of Burnley, on the Lancashire & Yorkshire railway. Pop. (1901) 15,920. It has iron and brass foundries, machine factories and textile establishments.

RAMSDEN, JESSE (1735–1800). English astronomical instrument maker, was born at Salterhebble near Halifax, Yorkshire, on the 6th of October 1735. After serving his apprenticeship with a cloth-worker in Halifax, he went in 1755 to London, where in 1758 he was apprenticed to a mathematical instrument maker. About four years afterwards he started business on his own account and secured a great reputation with his products. He died at Brighton on the 5th of November 1800. Ramsden’s speciality was divided circles, which began to supersede the quadrants in observatories towards the end of the 18th century. His most celebrated work was a 5-feet vertical circle, which was finished in 1789 and was used by G. Piazzi at Palermo in constructing his well-known catalogue of stars. He was the first to carry out in practice a method of reading off angles (first suggested in 1768 by the duke of Chaulnes) by measuring the distance of the index from the nearest division line by means of a micro-meter screw which moves one or two fine threads placed in the focus of a microscope. Ramsden’s transit instruments were the first which were illuminated through the hollow axis; the idea was suggested to him by Prof. Henry Ussher in Dublin. He published a Description of an Engine for dividing Mathematical Instruments in 1777.

RAMSEY, a market-town in the Northern or Ramsey parliamentary division of Huntingdonshire, England, on the south-western border of the Fen country, on branch lines of the Great Northern and the Great Eastern railways, 13 m. S.S.E. of Peterborough. Pop. of urban district (1901) 4,823. The fine church of St Thomas à Becket is transitional between Norman and Early English, and has a beautiful Norman east end. The tower was built in 1672 of stone from Ramsey Abbey. An old oak lectern, dating from the middle of the 15th century, carries a chained copy, in a Tudor binding of brass, of Dean Comber’s (1655–99) book on the Common Prayer, and a black-letter copy of Erasmus’s Paraphrase of the Gospels. There are many interesting tombs in the churchyard, and the church register contains several entries relating to the Cromwell family, who removed hither from Huntingdon and owned the abbey estates till 1674. Of the ancient Benedictine abbey the only remains are a part of a gateway, a lodge (a beautiful Perpendicular relic) and some buttresses, while some broken stone arches and walls remain of the conventual buildings. The modern mansion of Ramsey Abbey contains many documentary relics of the abbey, as well as an early monument representing the founder.

According to a 12th-century chronicle of one of the monks, the name Ramsey is derived from the words “ram,” referring to the tradition of a solitary ram having taken up its abode here, and “ey” meaning an island. Ramsey, however, was not completely insulated, like some of the monasteries of the Fen district. The abbey was founded by Ailwin, earl of the East Angles, in 969, and a charter of King Edgar granted lands and privileges for the purpose. Ramsey Abbey was noted for the school established within its walls, and for its library of Hebrew works. Its abbot was mitred. The lands were granted after the dissolution to Sir Richard Cromwell.

RAMSEY, a seaport and watering-place on the north-east coast of the Isle of Man, 15 m. N.N.E. of Douglas. Pop. (1901) 4,729. It lies on the wide Ramsey Bay, at the mouth of the Sulby river, the estuary of which forms a small harbour. To the north and west the country is flat, but to the south the lower slopes of the North Ballure hill rise sharply. A creek of the Sulby river on the north side of the town is formed into a picturesque lake. The Queen’s pier permits of the landing of passengers at all times, and Ramsey is served by
frequent steamers from Liverpool and other ports. The shore of the bay is sandy and gently sloping, and excellent bathing is afforded. A golf links, a geological and antiquarian museum, the Mooragh Park by the side of the lake, and the palace or concert hall, are among the attractions to visitors. Ramsey is connected with Laxey, the summit of Snaefell, and Douglas by electric tramway, and has connexion with the western part of the island by the Manx Northern railway. The Albert tower, on a wooded hill above the town, commemorating a visit of the Prince Consort in 1847, is a favourite view-point. The harbour has some coasting and fishing trade.

**RAMSGATE,** a municipal borough, watering-place, seaport and member of the Cinque Port of Sandwich, in the Isle of Thanet parliamentary division of Kent, England, 79 m. E. by S. of London by the South Eastern & Chatham railway. Pop. (1901) 27,733. This is one of the most popular resorts on the Kent coast, well situated on the east coast of Thanet, practically contiguous with Broadstairs to the north, with which and Margate to the west it is united by an electric tramway. During the season steamers connect it with London and the intermediate watering-places on the north coast, and with Calais and Boulogne. The harbour has an area of 43 acres, and a considerable coasting and fishing trade is carried on. There is a fine sea front, and the beach is of firm sand. The promenade pier was erected in 1881. Near it an obelisk commemorates the departure of George IV. to Hanover from here, and his return, in 1821. The church of St George was built in 1826, its tower forming a conspicuous landmark, and the Roman Catholic church of St Augustine was built from the designs and at the expense of A. W. Pugin, who was long a resident here. The neighbouring Pegwell Bay, famed for its shrimps, is supposed to have been the scene of the landing of Hengist and Horsa, and at Cliff's End (Ebbs Fleet) a monolithic cross marks the landing-place of St Augustine in 596. On the summit of Osengal Hill, about a mile to the west of the town, a graveyard of early Saxon settlers was discovered during the cutting of the railway. The remains proved it belonged to the 5th and 6th centuries. Ramsgate was incorporated in 1884, and is governed by a mayor, 5 aldermen and 18 councillors. Area, 2304 acres.

Ramsgate (Ramsesgate) was originally a small but comparatively prosperous place united until 1827 to the parish of St Lawrence. The charter of Charles II. mentions it as having been "time of mind" a member of Sandwich. In 1884 it was incorporated by royal charter, under the title of mayor, aldermen and councillors. A commission of the peace was granted in 1863. Since then the jurisdiction of the Cinque Ports' justices has ceased within its limits, which include the parishes of Ramsgate and St Lawrence Intra. A daily market was obtained in 1784 by grant from George III. No fair was then held, but from 1792 onwards there has been one yearly on the 20th of August. Under Queen Victoria, Ramsgate was still famous as the scene of a fair before the reign of Henry VIII. After 1668 the growth of trade increased its prosperity, and at the beginning of the reign of George I. the pier was enlarged and pier-wardens appointed to collect the droits. In 1749, having been selected as a Harbour of Refuge for the Downs, it underwent great improvements, and henceforward paid £200 yearly to Sandwich out of the droits for clearing the Channel and repairing the banks of the river Stour within the Liberty; but by 1790 the harbour was of small account.

**RAMSONS**, in botany, the popular name for Alliumursinum, a bulbous plant 6 to 18 in. high, with ova- lanceolate stalked leaves tapering at the apex, surrounding a naked stalk bearing a flat-topped umbel of small white flowers. A rather pretty plant, common in woods and in hedgebanks in spring, but with a pungent garlic-like smell, which is characteristic of the genus (see above). **RAMUS, PETRUS,** or **PIERRE DE LA RAMÉE** (1515-1572), French humanist, was born at the village of Cuth in Picardy in 1515, a member of a noble but impoverished family; his father was a charcoal-burner. Having gained admission, in a menial capacity, to the college of Navarre, he worked with his hands by day and carried on his studies at night. The reaction against scholasticism was still in full tide; it was the transition time between the old and the new, when the eager and forward-looking spirits had first of all to do battle with scholastic Aristotelianism. Ramus outdid his predecessors in the impetuousness of his revolt. On the occasion of taking his degree (1536) he actually took as his thesis "Everything that Aristotle taught is false." This tour de force was followed up by the publication in 1543 of Aristotelicae Animadversiones and Dialecticae Partitiones, the former a criticism on the old logic and the latter a new textbook of the science. What are substantially fresh editions of the Partitiones appeared in 1547 as Institutiones Dialecticae, and in 1548 as Scholae Dialecticae, his Dialectique (1555), a French version of his system, is the earliest work on the subject in the French language. Meanwhile Ramus, as graduate of the university, had opened courses of lectures; but his audacities drew upon him the hostility of the conservative party in philosophy and theology. He was accused of undermining the foundations of philosophy and religion, and the matter was brought before the parliament of Paris, and finally before Francis I. By him it was referred to a commission of five, who found Ramus guilty of having "acted rashly, arrogantly and impudently," and interdicted his lectures (1544). He withdrew from Paris, but soon afterwards returned, the decree against him being cancelled through the influence of the cardinal of Lorraine. In 1551 Henry II. appointed him professor of philosophy and eloquence at the Collège de France, where for a considerable time he lectured before audiences numbering as many as 2000. He published fifty works in his lifetime and nine appeared after his death. In 1561, however, the enmity against him was fanned into flame by his adoption of Protestantism. He had to flee from Paris; and, though he found an asylum in the palace of Fontainebleau, his house was pillaged and his library burned in his absence. He resumed his chair after this for a time, but in 1568 the position of affairs was again so threatening that he found it advisable to ask permission to travel. Returning to France he fell a victim to his opponents in the massacre of St Bartholomew (1572).

The logic of Ramus enjoyed a great celebrity for a time, and there existed a school of Ramists boasting numerous adherents in France, Germany and Holland. As late as 1656 P. Burgersdyk divides the logic of his day into two schools: the Semi-Ramists, who endeavoured, like Goclenius of Marburg, to mediate between the contending parties. Ramus's works appear among the logical textbooks of the Scottish universities, and he was one of the first to introduce Latitudinarianism. There is even a little treatise from the hand of Milton, published two years before his death, called *Artis Logicae Pleniori Institutio ad Petri Rami Methodum connectit.* It cannot be said, however, that Ramus's innovations mark a new stage in the history of logic. His so-called logical leaning is seen in the definition of logic as the "ars discernendi:" he maintains that the rules of logic may be better learned from observation of the way in which Cicero persuaded his hearers than from a study of the Organon. The division of the syllogism into natural and empirical was a rash attempt to reduce the art of logic, so that a single syllogistic method would serve for all. This division gave rise to the jocular designation of judgment or mother-wit as the "secunda Petri." He is, perhaps, most suggestive in his emendations of the syllogism. He admits only the first three figures, as in the orthodox Aristotelian school, and he also attacks the validity of the third figure, following in this the precedent of Laurentius Valla. Ramus also set the modern fashion of deducing the figures from the position of the middle term. He was the first to discriminate, upon the different relation of the middle to the so-called major and minor term. On the whole, however, though Ramus may be allowed to have advanced logical study by the wholesome fermentations which he was instrumental in stirring up, his pretentious claim to supersede Aristotle by a new and independent system is not borne out by results.

RAMUSIO. The noble Italian family of Ramusio—the spelling adopted in the publication of the Navigazioni, though it is also written Ramusius, Ramussio, Ramonussio, &c.—was one of note for literary and official ability during at least four generations. Its original home was in Rimini, and the municipality of that city has within the last few years set up a tablet on the town hall bearing an inscription which may be thus rendered: “The municipality of Rimini here records the claim of their city to the family of the Ramusios, adorned during the 15th and 16th centuries by the illustrious jurist and man of letters Paolo the elder, who rendered the work of Valturius, our fellow-citizen, into the vernacular; by the physician Girolamo, a most successful student of medical tongues, and the first to present Europe with a translation of Avicenna; and by Giovanni Battista, cosmographer to the Venetian republic and secretary to the Council of Ten, who bequeathed to the world that famous collection of voyages and travels, regarded in his own day as a marvellous work, and still full of authority among all civilized nations.”

**Paolo the Elder** (c. 1443–1506), the first of those thus commemorated, migrated in 1458 from Rimini to Venice, where he obtained full citizenship, studied law and became a member of the magistracy, filling the offices of vicario, of judicial assessor, and of criminal judge under various administrators of the Venetian provinces on the continent. He continued, however, to maintain relations with the Malatesta princes of his native city, and in 1503 negotiated with them the cession of Rimini to the republic. The wife of Paolo, bearing the singular name of Tomysir Macarchio, bore him three sons and four daughters. Paolo died at Bergamo on 10th August 1506 at the age of sixty-three, and was buried in S. Agostino at Padua. Paolo was the author of a variety of legal treatises and the like, and also published at Verona in 1483 both a corrected edition and an Italian translation of a once famous book, Valturius, De re militari, dedicating both to Pandolfo Malatesta of Rimini.

**Girolamo** (1450–1486), younger brother of Paolo, had a notable history. After he had studied medicine at Padua public suspicion was roused against him in connexion with the death of a lady with whom he had had some love passages, and this ran so high that he was dain, by help of his brother Paolo, to whom he transferred his property, to make his escape (about 1481–1483) to Syria and to take up his abode at Damascus. In 1486 he removed to Beirut, and died the same year, killed, as the family chronicler relates, by a surfeit of “certain fruit that in that country are known as mazzafrenchi,” a title which English sailors in southern regions still give to apricots in the vernacular phrase of killjohns. During his stay in Syria Girolamo studied Arabic and made a new translation of Avicenna, or rather, we may assume, of some part of that author’s medical works (the Canon?). It was, however, by no means the first such translation, as is erroneously alleged in the Rimini inscription, for the Canon had been translated by Gerard of Cremona (d. 1187), and this version was frequently issued from the early press. Girolamo’s translation was never printed, but was used by editors of versions published at Venice in 1570 and 1606. Other works of this considerable member of the house of Ramusio consisted of medical and philosophical tracts and Latin poems, some of which last were included in a collection published at Paris in 1571.

**Gian Battista** (1485–1557), the eldest son of Paolo Ramusio and Tomysir Macchario, was born at Treviso in 1485 (June 30). Having been educated at Venice and at Padua, at an early age he entered the public service (1503), becoming in 1515 secretary of the senate and in 1533 secretary of the Council of Ten. He also served the republic in various missions to foreign states, e.g. to Rome, to Switzerland and to France, travelling over much of the latter country by special desire of the king, Louis XII. He also on several occasions filled the office of cancellier grande. In 1534 he married Franceschina, daughter of Francesco Navagero, a noble—a papal dispensation being required on account of her being cousin to his mother Tomyria. By this lady he had one son, Paolo. In his old age Ramusio resigned the secretariage and retired to the Villa Ramusia, a property on the river Masanga, in the province of Padua, which had been bestowed on his father in 1504 in recognition of his services in the acquisition of Rimini the year before. The delights of this retreat are celebrated in the poems and letters of several of Gian Battista’s friends. He also possessed a house at Padua in the Strada del Patriarca, a mansion noted for its paintings and for its collection of ancient sculpture and inscriptions. These, too, are commemorated by various writers. A few days before his death Ramusio removed to this house in Padua, and there died, 10th of July 1557, at the age of seventy-two. He was, by his own desire, buried at Venice, in the tomb which he had made for his mother, in Santa Maria dell’ Orto. His wife’s death had occurred in 1536. In the work called Museum Mazzuchelianum (Venice, 1561, vol. i. pl. lxiv. No. 6) there is represented a 16th-century medal of Ramusio, which looks a genuine likeness, and a bronze example of which, without the reverse, is preserved in St Mark’s Library. There was a portrait of him, represented as in conversation with Andrea Gradengo, in the Sala del Magnior Consiglio, but in 1577 this perished in a fire, as did also a portrait of his father, Paolo. A posed portrait of Gian Battista by Francesco Griselli, in the Sala dello Scudo, appears to be like the companion portrait of his father, Paolo, a work of fancy. A public nautical school at Rimini received from the government the title the Istituto Ramusio.

Ramusio was evidently a general favourite, as he was free from pushing ambition, modest and ingenuous, and, if it be safe to judge from some of the dissertations in his Navigazioni, must have been a delightful companion; both his friend Giunti and the historian Giustinianii speak of him with the strongest affection. He had also a great reputation for learning. Before he was thirty Aldus Manutius the elder dedicated to him his edition of Quintilian (1514); a few years later (1510) Francesco Ardano inscribed to him an edition of Livy, and in 1528 Bernardino Donati did the like with his edition of Macrobius and Censorinus. To Greek and Latin and the modern languages of southern Europe he is said to have added a knowledge of Oriental tongues, but there is no evidence of Ramusio’s acquaintance with the languages of the East, and no authority has been adduced for the statement that he was selected in 1530 on account of this accomplishment to investigate the case of one David, a Hebrew, who, claiming to be of the royal house of Judah, wished to establish himself at Venice outside of the Ghetto. But Ramusio had witnessed from his boyhood the unrolling of that great series of discoveries by Portugal and Spain in East and West, and the love of geography thus kindled in him

1 Both works are in the British Museum.
2 “Ramusio saepe de Sereni et Calcidio,” but which in that country are known as mazzaranchi,” a title which English sailors in southern regions still give to apricots in the vernacular phrase of killjohns.
3 The reverse is an amorphous map. The book is in the British Museum.
4 Rerum Venetarum ... Historia, bk. xiv.
5 Ramusio’s report on this Hebrew is preserved in the diaries of Marcus Sanudo, and is printed by Cigogna. It is curious. David represented himself as a prince of the Bedouin Jews who haunt the camel-road between Damascus and Medina; he claimed to be not only a great warrior covered with wounds but great also in the law and in the cabala, and to have been inspired by God to conduct the dispersed tribes to the Holy Land and to rebuild the temple. In this view he had visited Prester John and the Jews in his kingdom, and then various European countries. David was dark in complexion, “like an Abyssinian,” lean, dry and Arab-like, well dressed and well attended, full of pretensions to supernatural cabalistic knowledge and with a most fine figure. The British Museum regarded him as a veritable Messiah.
made that branch of knowledge through life his chief study and delight. He is said, with the assistance of friends touched by the same flame, to have opened a school for geography in his house at Venice. And it appears from a letter addressed to him by his friend Andrea Navagero, that as early as 1523 the preparation of material for his great work had already begun. The task had been suggested and encouraged, as Ramusio himself states in a dedicatory epistle to the famous Girolamo Fracastoro, by that scholar, his lifelong friend, an address to the same personage indeed introduced each of the three volumes, and in the first the writer speaks of his desire to bequeath to posterity, along with his labours, "a testimony to the long and holy friendship that had existed between the two." They were contemporaries in the strictest sense (Ramusio 1485-1557, Fracastorius 1483-1553). His correspondence, which was often devoted to the collection of new material for his work, was immense, and embraced many distinguished men. Among those whose names have still an odour of celebrity were Fracastoro, just mentioned, Cardinal Pietro Bembo, Damianio de Goz, and Sebastian Cabot; among lesser lights, Vettor Fanzo, Daniel Barbaro, Collo Maruzio, Andrea Navagero, the cardinals Gasparo Contarini and Gregorio Cortese, and the printer Tommaso Giunti, editor after Ramusio's death of the Navigazioni.

Two volumes only of the Navigationi e Viaggi were published during the life of Gian Battista, vol. i. in 1550, vol. iii. in 1556; vol. ii. did not appear till 1559, two years after his death, delayed, as his friend and printer T. Giunti explains, not only by that event but by a fire in the printing-office (November 1557), which destroyed a part of the material which had been prepared. It had been Ramusio's intention to publish a fourth volume, containing, as he mentions himself, documents relating to the Andes, and, as appears from one of the prefaces of Giunti, others relating to explorations towards the Antarctic.1 Ramusio's collection was by no means the first of the kind, though it was, and we may say on the whole continues to be, the best. Even before the invention of the press such collections were known, of which that made by a certain Long John of Ypres, abbot of St Bertin, in the latter half of the 14th century was most meritorious, and afforded in its transcription a splendid field for embellishment by the miniaturists, which was not disregarded. The best of the printed collections before Ramusio's was the Novus Orbis, edited at Basel by Simon Grynaeus in 1532, and reissued in 1537 and 1555. This, however, can boast of no disquisitions nor of much editorial judgment. Ramusio's collection is in these respects far superior, as well as in the variety and fulness of its matter. He spared no pains in ransacking Italy and the Spanish peninsula for contributions, and in translating them when needful into the racy Italian of his day. Several of the pieces are very rare in any other shape than that exhibited in Ramusio's collection; several besides of importance—e.g. the invaluable travels of Barbosa and Pigafetta's account of Magellan's voyage—were not publicly known in any complete form till the present century. Of two important articles at least a new edition is urgently needed (otherwise preserved or discovered; one of these is the Summary of all the Kingdoms, Cities, and Nations from the Red Sea to China, a work translated from the Portuguese, and dating apparently from about 1553; the other, the remarkable Ramusian redaction of Marco Polo (q.v.). The Prefazione, Esposizione and Dichiarazione, which precede this version of Marco Polo's book, are the best and amplest examples of Ramusio's own style as an editor. They are full of good sense and of interesting remarks derived from his large reading and experience, and few pictures in words were ever touched more delightfully than that in which he sketches the return of the Polo family to their native city, as he had received it in the tradition of the Venetian elders.

There were several editions of the Navigationi e Viaggi, and as additions continued to be made to the several volumes a good deal of bibliographical interest attaches to these various modifications.2 The two volumes (i. and iii.) published in Ramusio's lifetime do not bear his name on the title-page, nor does it appear in the addresses to his friend Fracastorius with which these volumes begin (as does also the second and posthumous volume). The editions of vol. i. are as follows: 1550, 1554, 1563, 1588, 1606, 1613.3 The edition of 1554 contains the following articles which are not in that of 1550: (1) copious index; (2) "Narr. di un Compagno di Barbosa"; (3) "Informazioni del Giapan"; (4) "Alli Lettori di Giov. de Barros"; (5) "Capiotli estratti da di Barros." The edition of 1563 adds to these a preliminary leaf concerning Ramusio, "Tommaso Giunti alli Lettori." After 1563 there is no change in the contents of this volume, only in the title-page. It should be added that in the edition of 1554 there are three double-page woodcut maps (Africa, India and India extra Ganges), which do not exist in the edition of 1550, and which are replaced by copperplate maps in subsequent editions. These maps are often missing. The editions of vol. ii. are as follows: 1559, 1574, 1583, 1606. There are important additions in the 1574 edition, and still further additions in that of 1583. The additions made in 1574 were: (1) "Herberstein, Della Moscovia e della Russia"; (2) "Viaggio in Persia di Caterino Zeno"; (3) "Scopimento dell' Isola Frislanda, &c., per due fratelli Zeni"; (4) "Viagg in Tartaria per altr frati Minori"; (5) "Viaggio del Beato Odorico" (two versions). Further additions made in 1583 were: (1) "Navigazione di Seb. Cabota"; (2) at the end 90 ff. with fresh pagination, containing ten articles on "Sarmatia, Polonia, Lithuania, Prussia, Livonia, Moscovia, and the Tartars by Aless. Guagino and Matteo di Micheove." The two latest "editions" of vol. ii. are identical, i.e. from the same type, with a change of title-page only, and a reprint of the last leaf of the preface and of the last leaf of the book. But the last circumstance does not apply to all copies. In one, whilst the title bears 1606, the colophon bears "Appresso i Giunti, 1583." Vol. iii. editions are of 1556, 1565 and 1606.4 There is no practical difference between the first two, but that of 1606 has forty-five pages of important new matter, which embraces the Travels of Cesare Fedrici or Federici in India, one of the most valuable narratives of the 16th century, and Three Voyages of the Hollanders and Zealanders to Nova Zembla and Groenland. Vol. iii. also contains (omitting maps and figures inserted in the text, or with type on the reverse) a two-page topographical view of Cuzco, a folding map of Terra Nova and Labrador, a two-page map of Brazil, a two-page map of Guinea, &c., a two-page map of Sumatra, a two-page pictorial plan of the town of Hocelaga in New France, and a general map of the New World in a hemisphere. Brunet's statement mentions issues of vol. iii. in 1564, and of vol. iii. in 1613; but these seem to have no existence. It would thus appear that a set of Ramusio, to be as complete as possible, should embrace—for vol. i., 1563 or any subsequent edition; for vol. ii., 1583 or 1606; for vol. iii., 1606.

1 See in vol. iii. the end of Ramusio's Discorsio on the conquest of Peru, and Giunti's "Alli Lettori" in the 3rd edition of the first volume.

2 Brunet's statements on the subject are borrowed, and not quite accurate. The detail in Cigogna seems to be accurate, but it is vague as to the deficiencies of the earlier editions.

3 All of these are in the British Museum.

4 All at the British Museum.

5 This person and his son affected the spelling Ramusso.
of apparently who historian Villehardouin; Cigogna. 1577, 83 of energetic position abroad. and 1884, he marriages, gress.

Though orthodox a standard Ramusio, was reared in the British Museum. 

RANADE, MAHADEO GOVIND (1842-1901), Indian lawyer, reformer and author, was born on the 16th of January 1842 at Niphad, in Nasik district, of a Chitpavan Brahman family. When his father was minister at Kolhapur he attended the Anglo-vernacular school in that town, and joined the Elphinstone Institute in Bombay at the age of fourteen. He was one of the first graduates of the Bombay University, taking the B.A. in 1862 and the LL.B. in 1866. Having entered government service he became presidency magistrate and then fourth judge of the small cause court at Bombay in 1871, first-class sub-judge at Poona in 1873, and judge of the Poona small cause court in 1884, after which, as special judge under the Deccan Agriculturists' Relief Act from 1889, he came into close contact with the difficulties of the agrarian classes. In 1886 he was a member of the finance committee appointed to report on the expenditure, both imperial and provincial, with a view to retrenchment. This service won him the decoration of C.I.E. He became a member of the legislative council of Bombay in 1885, and occupied that position until raised to the high court in 1893. Being an energetic social reformer, he directed his efforts against infant marriages, the shaving of widows, the heavy cost of marriages and other social functions, and the caste restrictions on travelling abroad. He strenuously advocated widow remarriage and female education. He was the founder of the social conference movement, which he supported till his death. In the political sphere he founded the Poona Sarvajank Shaba, through which he frequently helped the government with sound advice. He was also one of the originators of the Indian National Congress. In Bombay University, where he held the offices of syndic and dean in arts, he displayed much organizing power and the indifference to the need for intimacy with the needs of the student class. Himself a thorough Marathi scholar, he encouraged the translation of standard English works, and tried, with some success, to introduce vernacular languages into the university curriculum. Though reared in the strictest tenets of Hinduism, his deep religious feeling and trained intellect craved something higher and broader than he could find in the traditional forms and orthodoxy teaching of his race. The same spiritual want being felt by many enlightened Hindus, he joined with his friends, Dr. Atmaram Pandurang, Bal Mangesh Wagle and Vaman Abaji Modak, in founding a new sect in Bombay known as the "Parthana Samaj." This community resembles, in all essential points, the Brahma Samaj of Bengal. Its principles of enlightenment is based on the ancient Vedas. He published books on Indian economics and on Mahratta history. He died on the 16th of January 1901. He left no children, but his widow continued his work of social and educational reform at Poona.

See G. A. Mankar, Justice M. G. Ranade (Bombay, 1902).

RANAVALO (RANAVALONA) III. (1864- ), the last queen of Madagascar, born in 1864, was a great-niece of Radama I. Her name originally was Razândrâhêty, but on succeeding to the throne of Madagascar after the death of Queen Ranavalo II., on the 14th of July 1893, she assumed the style of Ranavalo III. Although nominally queen, she took no share in the government, which her prime minister, Rainilaiarivony, had controlled since 1864. After placing her on the throne, he married her before the close of the year. Ranavalo became queen just after the French had revived their claim to a protectorate over the island. The Hova government refusing to admit the claim, war broke out, and several sharp engagements took place. The French bombarded the coast towns, but were unable to reach the interior of the island, where the strength of the Hova lay. In December 1885 a treaty was concluded by which it was agreed that the government of the French Republic should represent Madagascar in all foreign relations, but that in internal matters the Hova government should be independent, as formerly. During the next ten years French influence was quietly extended over the island, in spite of the efforts of Rainilaiarivony, who pursued an anti-French policy, encouraging English and American planters and traders. In 1894 differences on commercial and territorial questions arose between the Hova government and the French, which terminated in war. In 1895 a well-organized expedition was despatched from France to subjugate the island. Many of the inhabitants sympathised with the invaders, and even the Hova themselves were divided. Although Ranavalo endeavoured to arouse a martial spirit in her subjects, the French advanced on the capital without encountering any effective opposition. On the 30th of September they captured Antananarivo. Rainilaiarivony was sent into exile, where he died in the following year; but Ranavalo was suffered to remain as nominal head of the government, under a strict French protectorate. In August 1896, to avoid commercial difficulties with foreign powers, the island was declared a French colony; but no change was made in the internal administration. Later in the year, however, the civil governor was replaced by a military resident, General Gallieni. A formidable insurrection broke out, which Gallieni suppressed, executing or exiling several prominent members of the Hova administration. Finding that the court had been a centre of intrigue, he abolished the sovereignty by proclamation in February 1897, and exiled Ranavalo to Reunion. In March 1899 she was removed to Algiers. Her exile there was relieved by occasional visits to Paris.

RANC, ARTHUR (1831-1908), French politician and writer, was born at Pottiers on the 20th of December 1831, and was educated for the law. Implicated in a plot against Napoleon III. in 1853, he was acquitted, but shortly afterwards was imprisoned for belonging to a secret society; for his share in anti-imperialist conspiracies in 1855 he was arrested and deported to Algeria without a trial. The amnesty of 1859 permitted him to return to Paris, where he soon drew the attention of the police to his presence by his violent articles. During the siege of Paris he left the city in a balloon and joined Gambetta, for whom he organized a system of spies through which General Trochu was kept informed of the strength and disposition of the Prussians around Paris. He was elected to the National Assembly in February 1871, but resigned rather than subscribe to the peace. He had been elected mayor of the ninth arrondissement of Paris in the autumn of 1870, and in March was sent by the same district to the Commune, from which he resigned when he found no reconciliation was possible between the mayors and the Commune. In July he became a member of the municipal council of Paris, and in 1873 was returned to the National Assembly for the department of the Rhône, and took his place on the extreme Left. A month after his election the governor of Paris demanded his prosecution for his share in the Commune. The claim being granted by a large majority, he
escaped to Belgium, where he issued a pamphlet defending his action during the Commune. On his failure to appear before the court he was condemned to death, and remained in Belgium until 1870, when he was included in the amnesty proclaimed by Grévy. During his exile he continued his active collaboration to _La République française_. In 1873 he fought a duel with Paul de Cassagnac, and he acted as second to Clémenceau more than once. He energetically defended the republic against the Boulangist agitation, and took an equally courageous part in the Dreyfus affair. In the Picquart-Henry duel he was second to Colonel Picquart. He succeeded Clémenceau as editor of the _Aurore_, in which Zola's letter "J'accuse" had appeared, and was president of the Association of Republican Journalists. In 1903 he became senator for Corsica, and died on the 10th of August 1908.

In addition to his purely political writings, Arthur Ranc published political novels of the Second Empire, _Sous l'Empire_ (1872) and _Le roman d'une conspiration_ (1866).

**RANCÉ, ARMAND JEAN LE BOUTHILLIER DE** (1666-1700), founder of the Trappist Cistercians. He was born in Paris of a noble and influential family of Normandy; hence, being destined to the ecclesiastical state, he was when ten years old commendatory abbey of La Trappe and two other abbeys, prior of two priories, and canon of Notre Dame, Paris. At 30 he undertook the translation of Ancrenon. He went through his course of theological studies with great distinction, defeating Bossuet at the Baccalauréat in theology. He was ordained in 1651, and embarked on the ambitious and worldly career of a court abbé in the days of Louis XIV. But after a few years he underwent a complete change of life, and in 1662 he retired to his abbey of La Trappe, of which he became regular abbot in 1664 and introduced an austere reform (see _Trappists_). The best known episode of his subsequent life was the "Contestation" with Mabillon on the lawfulness of monks devoting themselves to study, which De Rancé denied. He resigned his abbacy in 1665, owing to declining health, and died in 1700.

The best of the early lives is that of P. le Nain, his sub-prior (1715); the most recent is by M. Serrant, _L'Abbe de Rancé et Bossuet_ (1903). A sufficient sketch is given by Helyot, _Histoire des ordres religieux_ (1718), vi. c. 1. _On the Contestation" on Monastic Studies, see Mainland, _Dark Ages, _§ x_.

**RANCH**, a term in current usage among the English-speaking peoples for a large farm, particularly one for cattle or horse-breeding. The word came into use in this application in the western states of North America, and was an adaptation of the Spanish-American _rancho_, herdsmen's huts; in Spanish a gathering of people having their meals in common, a mess.

**RANCHI**, a town and district of British India, in the Chota Nagpur division of Bengal. The town, which is situated on the Chota Nagpur plateau, about 2100 ft. above sea-level, is the headquarters of both the division and the district. Pop. (1901) 25,970. It is an important centre of local trade and the headquarters of the German Lutheran Mission. There are a high school and an industrial school, and it is proposed to found here a residential college for all Bengal. The cantonments, formerly called Doranda, accommodate a detachment of native infantry.

The **District of Ranchi**, formerly called Lohardaga after the town which was its headquarters, has an area of 7128 sq. m. It consists of two tabelandis, of which the higher rises to about 2000 ft. The whole area is broken by hills and undulations, which are terraced for rice. The steep slopes of hills are covered with a dense forest, where wild animals still abound, but no profit is derived from the timber. The principal rivers are the Subanarekhi and the North and South Koel. In 1901 the population was 1,187,925, showing an increase of 5.7% in the decade. Christians form 10% of the total. The district was affected by the famine of 1866-1867, and still more severely by that of 1900. Rice is everywhere the staple crop, with some millets and pulses. Tea cultivation has been introduced, but does not flourish. The only industry on a large scale is the manufacture of shellac. Myrobalans are also exported. Iron and soapstone are worked in small quantities. Hopes of profitable gold-mining in the quartz veins of the schist formation have proved abortive. There is no railway in the district, though surveys have been made to connect with the Bengal-Nagpur line.

See F. B. Bradley-Birt, _Chota Nagpur_ (1903).

**RAND, a Dutch word meaning border, edge, used in South Africa to designate a low rounded range of hills; specifically it is an abbreviated form of Witwatersand, an elevated ridge in the southern Transvaal, forming the water-parting between the basins of the Orange and Limpopo. The Rand is famous for its gold-bearing reefs (see _Gold_), and the word is often used as a synonym for the mining industry carried on over a great part of its area, or for Johannesburg (q.v.), the city which that industry created.

**RANDEL, SAMUEL JACKSON** (1828-1890), American politician, was born in Philadelphia, Pennsylvania, on the 9th of October 1828. He was educated in the public schools and in the University Academy, Philadelphia. In 1858-1859 he was a Democratic member of the state Senate. During the Civil War he served as a private in the Union army for ninety days in 1861, and two years later took part in the Gettysburg battle. In 1863 he was elected a Democratic representative in Congress. During the session of 1874-1875 he first gained a national reputation by the masterful manner in which he prevented the Republican majority from passing the Force Bill or Federal Election law. Under his leadership discipline and party harmony were established among the Democrats for the first time after the Civil War. He was speaker of the House from December 1876 to March 1881, during a period marked by rancorous debates concerning the disputed Hayes-Tilden presidential election. With the disappearance of the Reconstruction questions and the emergence of the tariff issue, however, his influence began to wane. As the leader of the Protectionist wing of the party he was superseded by the tariff reform advocates, such as John G. Carlisle, William R. Morrison, and Roger Q. Mills, Carlisle defeating him for the speakership in 1883. He died in Washington, D.C., on the 11th of April 1890.

**RANDAN**, a name for a boat rowed by three persons, stroke and bow using a single oar each and the central person a pair of oars. The word is of unknown origin, and can hardly be connected with a slanging word or a mere, which is found as early as the beginning of the 18th century and is generally taken as a variation of "random," haphazard.

**RANDAZZO**, a town of Sicily, in the province of Catania, at the N. foot of Mount Etna, 43 m. N. by W. of Catania by rail, and 26 m. direct. Pop. (1901) 11,798. It has considerable remains of architecture of the 13th and 14th centuries, including three Norman churches and some interesting palaces. The former contain some fine sculptures and goldsmith's work (Mauceri in _L'Arie_, 1906, 185). It is the nearest town to the summit of Etna (9 m.), and is one of the points from which the ascent may be made.

**RANDERS, a town of Denmark, capital of the amt (county) of its name in Jutland, on the Gudenaa at the point where it begins to widen into Randers Fjord, an inlet of the Cattegat. Pop. (1901) 29,057. The town is 15 m. from the open Cattegat and the harbour has 15 ft. depth on the bar. The chief exports are butter and eggs; the chief imports sugar, petroleum, coal and iron. Two railways run north to Aalborg, the Randers branch forming the main East Jutland line from the south, and an eastward branch serves Grenaa and Aabenraa on the coast. Though a place of considerable antiquity —being mentioned in 1086 as the meeting-place of insurgents against Knud, the saint —Randers has few remains of old buildings and bears the stamp of a compact, modern manufacturing town that owes its importance to its distilleries, manufactories of buildings, railway carriages, &c. St Marten's church dates from the 14th century, but was frequently altered and enlarged down to 1870. It has good woodwork of the 17th century. The high school is housed
RANDOLPH, E.—RANDOLPH, J.

in a medieval monastery, which was restored in 1894-97. There is a statue to Steen S. Bligh (1782–1849), the national poet and novelist. Rutland is best known in history as the scene of the assassination of Count Gerhard by Niels Ebbesen in 1340. In the middle ages it had six churches and four monastic establishments, the oldest a Benedictine nunnery (1170). The Grey Friars' building was turned into a castle (Dronningborg) after the Reformation; its church was burned down in 1608.

RANDOLPH, EDMUND JENNINGS (1753–1813), American statesman, was born on the 10th of August 1753, at Tazewell Hall, Williamsburg, Virginia, the family seat of his grandfather, Sir John Randolph (1603–1737), and his father, John Randolph (1727–84), who (like his uncle Peyton Randolph) were king's attorneys for Virginia. Edmund graduated at the College of William and Mary, and studied law with his father, who felt bound by his oath to the king and went to England in 1775. In August–October 1775 Edmund was aide-de-camp to General Washington. In 1776 he was a member of the Virginia Convention, and was on its committee to draft a constitution. In the same year he became the first attorney-general of the state (serving until 1786). He served in the Continental Congress in 1779 and again in 1780–82. He had a large private practice, including much legal business for General Washington. In 1786 he began to be prominent. In 1791 he had a second term of office as the governor of Virginia. He was a delegate to the Constitutional Convention of 1787, and on the 20th of May presented the "Virginia plan" (sometimes called the "Randolph plan").

In the Convention Randolph advocated a strongly centralized government, the prohibition of the importation of slaves, and a plural executive, suggesting that there should be three executives from different parts of the country, and refused to sign the constitution because too much power over commerce was granted to a mere majority in Congress, and because no provision was made for a second convention to act after the present instrument had been referred to the states. In October 1787 he published an attack on the Constitution; but in the Virginia convention he urged its ratification, arguing that it was too late to attempt to amend it without endangering the Union, and thinking that Virginia's assent would be that of the necessary ninth state. In 1788 he refused re-election as governor, and entered the House of Delegates to work on the revision and codification of the state laws (published in 1794). In September 1786 he was appointed by President Washington as attorney-general of the United States. He worked for the revision of Ellsworth's judiciary act of 1789, and especially to relieve justices of the supreme court of the duties of circuit judges, and advocated a Federal code; in 1791 he considered Hamilton's scheme for a national bank unconstitutional; and in 1792–93, in the case of Chisom v. Georgia before the supreme court, argued that a state might be sued by a citizen of another state. On the 2nd of January 1794 he succeeded Thomas Jefferson as secretary of state. In 1795 he wrote thirteen letters (signed "Germanicus") defending the President in his attack on the American Jacobin or democratic societies. He was the only cabinet member who opposed the ratification of the Jay treaty (his letters to the President on the subject are reprinted in The American Historical Review, vol. xii. pp. 587–590), and before it was ratified the delicate task of keeping up friendly diplomatic relations with France fell to him. Home despatches of the French minister, Joseph Fauchet, intercepted by a British man-of-war and sent to the British minister to the United States, accused Randolph of asking for money from France to influence the administration against Great Britain. Although this charge was demonstrably false, Randolph when confronted with it immediately resigned, and subsequently secured a retraction from Fauchet; he published A Vindication of Mr Randolph's Reservation (1793) and Political Truth, or Animadversions on the Past and Present State of Public Affairs (1796). He was held personally responsible for the loss of a large sum of money during his administration of the consular department, and on an indictment in the admiralty court was judged by an arbitrator to be indebted to the government for more than $49,000, which he paid at great sacrifice to himself. He moved to Richmond in 1803, and during his last years was a leader of the Virginia bar; in 1807 he was one of Aaron Burr's counsel. He died at Carter Hall, Millwood, Clarke county, Virginia, on the 12th of September 1813.

Moncure D. Conway, in his Omitted Chapters of History disclosed in the Life and Papers of Edmund Randolph (New York, 1888; 2nd ed., 1889), greatly exaggerates Randolph's work in the Constitutional Convention; the common view underestimates and makes him a "hair-splitter," and a man of no decision of character.

RANDOLPH, JOHN (1773–1833), of Roanoke, American statesman. He was a member of an influential and wealthy Virginian family, and was the third and youngest son of John Randolph of Lawsons, Chesterfield county, where he was born on the 2nd of June 1773. He was a descendant of John Rolfe and his wife Pocahontas. His father having died in 1775, his early years were passed under the care of his mother and his stepfather, Mr St George Tucker, from whom, however, he eventually became estranged, as he did from almost every one with whom he came in contact. He was educated at a school at Williamsburg, Virginia, and for a short time studied at Princeton and at Columbia; but, although well read in modern works bearing on politics and philosophy, his own statement, "I am an ignorant man, sir," was in other respects not inaccurate. Both his religious and his political views were radical and extreme. At an early period he imbied deistical opinions, which he promulgated with eagerness. He was also, though a mere boy when the new Federal government was organized in 1789, strongly opposed to the new Constitution of the United States. In order to assist in asserting the right of resistance to national laws, and to withstand the "encroachments of the administration upon the indisputable rights" of Virginia, he was in 1799 elected as a Republican to the national House of Representatives, of which he was a member, with the exception of two terms (1813–15 and 1817–19), until 1825, and again in 1827–29. After the accession of Jefferson to the presidency in 1801, Randolph was appointed chairman of the Committee of Ways and Means, and as such was naturally the leader of the Republican majority in the House. He took an active part in agitating for the reform of the judiciary, and in 1804 moved the impeachment of Judge Samuel Chase (q.v.), acting as the leader of prosecution in the trial before the Senate. Though an avowed Republican, he was far from being subservient to his party, and for several years after 1805 led a small faction, called "Quids," which sharply criticized Jefferson and attempted to prevent the selection of Madison as the
presidential candidate of his party. In March 1807 he lost the chairmanship of the Ways and Means Committee. Possessing considerable wit, great readiness, and a style of what bombastic eloquence, he would undoubtedly have risen to high influence but for his strong vein of eccentricity and his bitter and ungentlemanly temper. The championship of state's rights was carried by him to an extreme utterly quixotic, inasmuch as he not only asserted the constitutional right of Virginia to interpose her protest against the usurpation of power at Washington, but claimed that the protest should be supported by force. From December 1825 to March 1827 he served in the United States Senate, and in April 1826 he was forced to fight a duel with Henry Clay, on account of his violent abuse of that statesman in the course of a debate. In 1830 he was sent by President Jackson on a special mission to Russia, but remained in St. Petersburg only ten days, then spent almost a year in England, and on his return in October 1831 drew $21,407 from the United States Treasury for his services. He died of consumption at Philadelphia on the 24th of June 1833. Though his political life was full of inconsistencies—he was even capable of advancing the cause of nullification on one day and of opposing the passage of the same bill on the next—he generally adhered to the principles enunciated by the Republican party in its earliest years, and throughout his later career, in numerous speeches, he laboured to bring about the identification of slavery with the theory of states' rights. In this he was the natural precursor of Calhoun. His last will was disputed in the law courts, and the jury returned a verdict that in the later years of his life he was not of sane mind. He was always in theory opposed to slavery, and by the will which was accepted by the courts, freed his own slaves.

The best biography is that by Henry Adams, John Randolph (Boston, 1882), in the "American Statesmen Series." There is also a biography, which, however, contains many inaccuracies, by Hugh A. Garland (2 vols., New York, 1854).

**RANDOLPH, PEYTON** (1721-1775), American politician, was born at Tazewell Hall, Williamsburg, Virginia, in 1721, a son of Sir John Randolph (1663-1737), the king's attorney for Virginia. He graduated at the College of William and Mary, and studied law at the Inner Temple, London, and in 1748 was appointed the king's attorney for Virginia.1 Randolph wrote the address of remonstrance to the king in behalf of the Burgess against the suggested stamp duties in 1764. His policy was conservative and moderate, and in May 1765 he opposed Patrick Henry's radical "Stamp Act Resolutions." In 1766 he resigned as king's attorney and was succeeded by his brother John (1727-1784). In 1769 he acted as moderator of the privately convened assembly which entered into the non-importation agreement, and in May 1773 he became chairman of the first Virginia intercolonial committee of correspondence. He presided over the provincial convention of August 1774, and was a member of the First Continental Congress, of which he was president from the 3rd of September to the 22nd of October 1774. He was re-elected to Congress in March 1775, and on the 16th of May was again chosen to preside, but on the 26th he left to attend a session at Williamsburg of the Virginia Burgesses. He then returned to Congress, where John Hancock had meanwhile been made president. Randolph died of apoplexy in Philadelphia on the 22nd of October 1775. He was provincial grand-master of the Masons of Virginia, and was an intimate friend of Washington.

**RANDOLPH, THOMAS** (1523-1590), English diplomatist, son of Avery Randolph, a Kentish gentleman, was educated at Christ Church, Oxford, and in 1549 became principal of Pembroke College, Oxford, then known as Broadgates Hall. During

1 In 1574 the Burgesses sent him to London to argue against the governor's demand for a fee of one pistole on every land patent; his plea was successful, but the governor superseded him with George Wythe, who resigned in Randolph's favour upon his return from England. The Burgesses voted Randolph £200 with the grant of £20,000 to Governor Dinwiddie for Indian warfare; the governor would not approve this appropriation, however, until Randolph apologized for leaving his office without the governor's permission.
or the *primum mobile* of tradesmen, a walking-burse or movable exchange, a Socratic citizen of the vast universe, or a peripatetic journeymen, that, like another Atlas, carries his heavily shop on’ s shoulders.” He then proceeds to display his wares with a running satirical comment. *The Jealous Lovers* was presented by the students of Trinity College, Cambridge, before the king and queen in 1632. *The Muse’s Looking-Glass* is hardly a drama. Roscius presents the extremes of virtue and vice in pairs, and last of all the “golden mediocrity” who announces herself as the mother of all the virtues. *Amyntas, or The Impossible Dowry*, a pastoral printed in 1638, with a number of miscellaneous Latin and English poems, completes the list of Randolph’s authenticated work. *Hey for Honesty, down with Knavery*, a comedy, is doubtfully assigned to him.

His works were edited by W. C. Hazlitt in 1875.

**RANDOM** (older forms *randon*, *randrun*; from the French, *cl. randir*, to run quickly, impetuously; generally taken to be of Teutonic origin and connected with Ger. *Rand*, edge, brim, the idea being possibly of a brimming river), an adjective originally meaning impetuous, hasty, hence done without purpose or form, haphazard. The term “random work” is used, in architecture, by the rag-stone masons, for stones fitted together at random without any attempt at laying them in courses. “Random course work” is a like term applied to work course in horizontal beds, but the stones are of varying height, and fitted to one another (see MASONRY).

**RANELAGH**, formerly a popular resort by the Thames in Chelsea, London, England. About 1690 the land lying east of Chelsea Hospital, and bordering the river about the point where Chelsea Bridge now stands, was acquired by Richard, Viscount Ranelagh, later earl of Ranelagh (d. 1711). He built a mansion and laid out fine gardens, which, in 1742, were thrown open as a proprietary place of entertainment. A building called the Rotunda was erected for concerts, and the gardens quickly became a favourite resort of fashionable society. Balls and masquers, exhibitions of fireworks, regattas and many other forms of amusement were provided; but by the close of the 18th century Ranelagh was ceasing to attract the public, and in 1805 the Rotunda was closed. The buildings were removed, and the grounds became the property of Chelsea Hospital. They are still included in the pleasant gardens belonging to that foundation, but no traces of the popular Ranelagh are preserved. There is, however, a fashionable modern club of the same name.

**RANGE-FINDER.** Telemeter or Position-Finder (Fr. *télémètre*; Ger. *Distanzmesser*; It. *Telemetro*; Russ. *Dalnomier*; Span. *Telémetro*; in the United States the word telemeter is sometimes applied to the stadia used in connexion with the theodolite), an instrument, of which many varieties have been invented, for assisting the gunner and the infantry soldier in determining the distance or range* to their objective. Nearly all range-finders may be described as instruments which automatically solve a triangle. Usually it is a right-angled triangle, the length of the base of which is known, and one of the sides is the range it is desired to find. They are, in fact, goniometers, but the angle which they measure, whether it may be at the end of the measured base, or that subtended by it, is usually expressed as a function of the angle in terms of the measured base. Thus the range is recorded directly in metres or yards without calculation. It is proposed here to describe principally the range-finding instruments in the British services (1) as used in the fleet; (2) by the army in the field; (3) in harbour defence; and (4) to refer briefly to range-finders, not under these heads, of English and foreign design.

1. The necessity for a range-finder afloat caused the British Admiralty in 1891 to issue an advertisement in the press inviting inventors to produce an instrument which would, amongst other conditions, record ranges with an accuracy of within 3% at 3000 yds. The resulting competition was declared in favour of a range-finder which is the joint invention of Professor Barr of the Glasgow University and Professor Stroud of the Yorkshire College.

The naval range-finder consists of a tube* which contains two telescopes. It is carried on a frame by bearings, in which the tube is free to revolve about its longer axis. To the frame is attached a weight capable of movement within a tank. This weight balances the range-finder and frame upon knife-edges. By means of the handle on the left of the instrument and an altitude worm beneath it, the motion of the tube is governed, and the line of sight is directed on the objective. By partially filling the tank with water, the swinging of the weight in a sea way can be checked. The frame is supported on a pedestal and can rotate in azimuth upon it (fig. 1).

![Fig. 1.—Barr and Stroud.](image)

A rubber guard is fitted round the eye-pieces. Its functions are to guide the eyes of the observer into the correct position, and to protect them from side light and the distressing effect of wind. It also guards the forehead against the jar occasioned by firing heavy guns. The upper portion of the field presented to the left eye is used as a finder, the lower portion is occupied by the scale upon which the ranges are engraved. The finder is a low-power telescope of large field, to the centre of which the objective is brought. When the telescope is thus correctly aligned, the objective will be seen with the right eye largely magnified, but as two partial images separated by a thin black horizontal line. When coincidence of the images is effected by means of the working head, the range can be

1 The length of tube varies from 3 ft. in the smaller to 9 ft. in the larger instruments.
read off against a pointer from the scale seen with the left eye. For night use, means are provided for illuminating the scale. The range to lights may be ascertained by the use of the astigmatizer, an optical device by which a point of light is drawn out into a vertical streak. A beam of light from the objective falls on each reflector (fig. 2),

and passing through the object-glasses, each is received by an arrangement of prisms about the centre of the tube, and reflected through the eyepiece. These two partial images are thus seen. The images could be united by the rotation of one of the reflectors, but owing to the small base used the necessary movement would be so extremely small that it would be practically impossible to measure it. The difficulty has been surmounted by utilizing fixed reflectors and effecting coincidence by means of a prism of small angle. The deflecting prism is situated in the line of the beam of light from the reflector at the right-hand end of the tube. Its multiplying action is of great delicacy. The angle of division for subdivision fourths of the ranges between infinity and 250 yds., is only one-third of a degree.

In a travel of 6 in, the prism renders accurate measurements possible within the required limits. To bring images of distant objects into coincidence, the prism must be moved towards the eye-piece, and for this purpose a sliding movement is necessary. The range scale is attached to the prism. A consequent advantage is that the accuracy of the instrument is not affected by back lash arising from wear, or irregularity in the actuating mechanism. When once in position, the instrument is always ready for use. Should adjustment be required it is readily and easily applied. It is not within the sphere of this article to enter into the detail of the adjusting mechanism. For further particulars the reader is referred to the Proceedings of the Institution of Mechanical Engineers for January 1896. The working of the range-finder is so simple that its use is quickly learnt by any man who can read, and with little instruction and practice he can "take a range in 8 to 12 seconds. Besides its principal purpose, in connexion with gunnery, there are many uses in navigation and nautical surveying to which the range-finder can be applied.

With the high speeds of modern war-vessels, guns and their objectives are much further apart than in former times, and unless ranges can be communicated from the instrument to the guns with rapidity and accuracy the range-finder is deprived of much of its value. In connexion with the naval range-finder an apparatus is provided, which though not part of the range-finder is sufficiently important to claim passing notice. The apparatus consists of a transmitting and a receiving instrument of clockwork mechanism electrically controlled. In appearance they resemble the ordinary engine-room telegraph, on the dials of which ranges take the place of orders. The transmitting instrument can communicate with a number of receiving instruments, disposed as required in different parts of the ship.

2. Before the introduction of the Marindin range-finder described below, the British army in the field used the "mekometer." The instruments used by the cavalry and infantry are smaller and lighter than those of the artillery pattern, but the principle involved is identical.

The mekometer is practically a box sextant. Two instruments are used, one preciously at the ends of a base of fixed length. One sextant, called the right-angle instrument, is fitted with index and horizon glasses permanently inclined at 45°. It consequently measures a right angle. In the other sextant, called the reading instrument, a graduated drum takes the place of the usual index arm and scale. The drum is graduated spirally with a division of ranges. Both reading and right-angle instruments are fitted with a vane of gun metal with a white strip down the centre to facilitate observations. Telescopes of low power can be fitted to the instruments, and two of 50 (or 251) yds. are provided with which to measure the base.

Two observers attach the ends of the cord of fixed length (usually 50 yds.) to their instruments and separate until it is taut. The observer with the right-angle instrument moves into such a position that coincidence of image will be given between the objective and the vane of the instrument at the other end of the base, i.e. he makes ABC a right angle (fig. 3). Then the two right-angle sides are united, the observer at C turns the graduated drum of the reading instrument until the image of the vane of the right angle instrument coincides with the direction of the objective. The range AC is then read on the drum. The range BC on the drum are measures of the angle BAC when the base BC is 50 yds.

The mekometer is open to the objection which is common to all range-finders requiring more than one observer. There is always a danger that observers may cause coincidence on different objectives or on different parts of the same objective, and thus inaccuracy in the recorded range result. The instruments are expected to give an accuracy of less than 2 % at 2000 yds. For ranges over that distance, i.e. for usual artillery ranges, it is desirable to use a double prism (100 yds. in length), in which case the range registered on the drum must be doubled. This operation, although slight, is a distinct disadvantage, since it adds to the time of taking a range and is a possible source of error. For field artillery, however, a range-finder is only an auxiliary adjunct. The true range can be found by a process of trial and error (see Artillery) in as short a time as the mekometer observers take to report it. It must further be remembered that as shrapnel is the principal projectile of field artillery, not only the correct elevation but also the true length of time fuse has to be found. This the range-finder cannot do. Hence it is that the range-finder for field artillery, although a valuable auxiliary, is not of the same importance as in purely defensive positions, such as batteries for harbour defence, and land forts.

The Marindin range-finder was from 1908 gradually introduced in the infantry to replace the mekometer. It was the invention of Captain A. H. Marindin, of the Black Watch (Royal Highlanders). The principle of the instrument is that of coincidence, as in the Gautier Christie, Le Cyre, Souchier, and Barr and Stroud. But it differs from the last mentioned in that the right prism is made movable, and this movement (necessarily extremely small) is a function of the recorded range.

The steel tube, forming the base of the instrument, which carries the prism, is supported inside an aluminium outer tube in such a way that no direct shock is communicated to it. The appearance of the outside of the instrument, together with the names of the various parts, is shown in fig. 4.

The instrument can be used in two main positions, viz. horizontally, for ranging up objects, or vertically, for ranging on horizontal targets.

For instance, in the diagram (fig. 5) of a road running uphill, the instrument could be held in any of the three positions indicated,
at night, the two caps of the night-glasses should be opened. On looking through the instrument, any lamp or other light will appear like a fine, bright line, and the range can be taken in the ordinary way.

This range-finder possesses the superlative advantage of the one-man instrument, and it is claimed for it that it can range on horizontal objects, such as the crest of a hill, which has no detail suitable for use with a theodolite, and that it can be adjusted on service with no greater difficulty than the setting of a watch.

3. For harbour defence, owing to the long range of naval guns, and the fast targets which war-ships present, an accurate range-finder is of first importance. This is largely the case because ranged detected cannot be resorted to in the same manner as in the field, where the targets are comparatively motionless and the effective ranges are less. Successful artillery practice therefore depends, in a great measure, upon the range-finder.

The instrument used in harbour forts is known as the depression range-finder. As its name suggests, it solves a triangle in the vertical plane, of which the base is the height of the instrument above sea-level. Its appearance resembles some forms of theodolite (fig. 6). A framework, capable of rotating in azimuth on a vertical pivot, is supported on a plate carried by levelling screws, L, L, L, respectively. The arm EF is supported at P by a vertical screw H ending in a drum, upon which, in a spiral scale, the ranges are graduated. Motion in altitude is thus given to the telescope. The arm CD is supported by a slider G. This slider is set by a rack and pinion to the height above sea-level (represented on a scale of feet on EF) at which the instrument may be used. A telescope AB is suitably fitted in jaws at the top of the frame. There are spirit-levels at M and Q for adjusting purposes. The telescope is provided with cross wires which can be illuminated for night use. An azimuth circle X and pointer Y enable the direction of any vessel to be indicated, the range of which it is desired to know. The instrument rests on a base plate K, to which it is locked by the top-plate O. The observer directs the cross wires of the telescope upon the water-line of the objective, by means of the drum I and the azimuth handle P, the top of which just appears in the diagram. The reader watches the arrow on the drum and calls out the range as the figures arrive beneath it. The ranges are communicated to the officers at the guns by various devices, which differ according to local requirements.

Position-Finder.—The range-finding instrument known in the British service as the Position-Finder (invented by Colonel Watkin, C.B., R.A.) is practically a large depression range-finder. It possesses, however, certain additional appliances which render it capable of automatically recording, upon an oriented chart, the position or course of a vessel. And further, by electrical means it automatically records to a distant battery the range and bearing of the desired objective. The position-finder can therefore, from a concealed and safe position, automatically control the fire of a group of guns, whose detachments need not necessarily see the target engaged. As the observer follows the objective with the telescope of the instrument the range and bearing is simultaneously shown in the battery on convenient dials. The distance and direction thus communicated are the range and bearing from the guns, not as measured from the range-finder. The correction due to the displacement between gun and instrument is automatic. In localities where, an the height does not admit of using the depression system, an alternative arrangement is provided, known as the Horizontal Position-Finder. It is open to the objections common to two-man range-finders, and is only employed where necessity compels its use. Briefly, there are two observing stations at either end of a measured and electrically connected base. One is known as the transmitting and the other the receiving station; the latter contains the principal instrument, which usually is capable of independent use for medium and short ranges as a depression instrument.

It will be seen that the difference between the two systems is, that the first described solves the range triangle in the vertical, and the latter in the horizontal plane. There have been various methods proposed for using the position-finder. The best results are obtained by placing range and bearing dials on the gun-mounting in a position where they can be easily seen by the men elevating and training the gun. The gun is kept directed upon the objective and fired as quickly as it can be loaded. A Horizontal position-finder can be used, but without advantage, and instruments are issued to the Royal Navy for this purpose.

In the United States of America the term "position-finder" is used which gives vision in both as well as distance. This is substantially correct, but custom, in the British service, confines the use of the expression as defined above.

4. Various appliances, not strictly range-finders, are sometimes used to assist in estimating distance. The following examples are not without interest:-

Acoustic telemeters, depending upon the velocity of sound, are obviously unsuited to the requirements of modern warfare. The names of Thouvenin, Rédier and Le Boulené are connected with such instruments—that of the French engineer, Le Boulené, for instance, is perhaps the most convenient. It consists of a graduated glass tube filled with liquid, of suitable density, and containing a small metal traveller. At the flash of discharge of a gun or rifle the instrument is brought to a vertical position, and the traveller starts from zero; at the detonation, it is turned to a horizontal position and the traveller stops at the point on the scale indicating the range.

The principle is the rough method of ascertaining the distance, in yards, of a thunderstorm, viz., multiply the number of seconds elapsing between the perception of the lightning and that of the thunder by the number of days in the year.

Optical or periscope telemeters determine the distance to any point by observing the size of some object of known dimensions, as seen in a graduated telescope. Porro's telemeter, Elliott's telescope and Nordenfelt's micrometer illustrate the principle. The chief defect of the system is that the objects must be conveniently visible, in range therefore is 400 × 800 yds. it are considerably in size, so that the assumption of a constant dimension may be productive of error.

On the continent of Europe the perspective telemeter for military purposes has attracted attention in England. The French in their precise terminology call such an instrument "Stadia militaire," a term which at once distinguishes it from a "télémètre," and describes its nature. In rapid military sketching, in locating positions on maps, or in perspective guidance circles of charge, and the range of the instrument is often necessary. The French version is provided with a scale in the field of view. By comparing this scale with known heights, such as the average height of a man on foot, or the known height of a battery, &c., of a war-vessel, distance can be estimated with fair accuracy.

The "jumelle Souchier," which can be used as an ordinary field-glass, is constructed on the stadia principle. By means of ranges can be estimated, at least to within 10%. A stand or rest, however, is necessary for good results.

General Percin of the French army has shown, in an interesting pamphlet, that a piece of wood or card cut to a known fraction of the distance between the two eyes, when the arm is fully extended, can be used to estimate distances. Thus it is easy to find a penny in good condition of which the thickness is 1/4th part of the arm-length in a man of average height. Provided with such a coin an observer finds it to exactly cover a distant man 6 ft. (or 2 yds. high). Similarly, if the man's height appeared to be half the thickness of the coin the range would be 4 × 400 = 1600 yds. With a little practice the eye estimates the proportion between the object of
known height and the stadia used. General Percin gives many useful applications of this simple device.

Various range-finders have been produced in countries outside the British Isles which, as they are the outcome of similar necessity and required for identical purposes, naturally resemble, more or less, the instruments already described.

Field artillery officers of all countries usually claim their gun to be their best range-finder. This may be another way of saying that a cult exists of the invention of Colonel Soultier. It is possible that modern artillery ranges with accuracy, has yet to be invented. In France the "télemètre Goutier" for field artillery, a two-man instrument, corresponds with the Watkin mekometer.

The "Gautier," used by the Italian field artillery, is a one-man instrument on a measured baseline. The "Aubry" telemeter, used by some of the Russian batteries in Manchuria, is very portable, but requires a measured base-line, and a slide rule to find the range. In the French and Russian artillery the prisme- télemètre, a combination of Colonel Soultier's invention, is used. It is small, very light, and can be carried in the same manner as field-glasses.

French machine guns are ranged by the "télemètre instantané," an instrument of the Barr and Stroud type, with an aluminium base 1 m. in length.

For work in the field the modern tendency abroad is to follow Barr and Stroud. In Germany, Hahn, Goerz and Zeiss have produced handy and fairly light short base range-finders, in outward appearance no more similar to Marindin's instrument than an average meteorite.

The Zeiss range-finder, however, depends on the stereoscopic principle. It is open to the objection that best results can only be obtained with it by persons who are capable of seeing stereoscopically, and many possessors of this instrument (particularly in preparatory small proportion of the human race), stereoscopic vision may vary in power from day to day. Nevertheless the Zeiss range-finder has found favour in many countries, notably as the infantry range-finder for use on defences. Though in its early days the Barr and Stroud range-finder is very largely used throughout the world. In Italy a Barr and Stroud instrument, with the large base of 5 metres, was in 1908 under trial for coast artillery.

On the depression range-finder type in France, "le télemètre Dévé" is used at all the ports of abroad and upwards.

Brazil possesses, in the invention of Captain Mario Netto, an excellent range-finder. It is supplied to the harbour defences of that country. It is accurate, handy, easily transported and re-erected after removal, and is not destroyed by burst heavy guns-fire. The German coast range-finder of Hahn closely resembles the earlier Watkin instruments. In Italy the Amici instrument is being replaced by the Braccialine. The latter inventor has also made the country a military horizontal base instrument.

After extended competitive trials in the U.S.A. the Lewis depression range-finder has been found superior to others presented to the Range-Finding Committee, and is recommended for adoption. It is nearly or less similar to Marindin's, in size and average mean error of 24 yds. in the ranges recorded during the trials. The maximum range was 12,000 yds. and the height of base 135 ft.

The details of position-finders abroad, as in the British service, are of interest. There is little evidence of the resumed use of the recoupment of the French coast batteries, or the "telegiometro Sollier" of Italy. In the United States, B. A. Fiske has ingeniously adapted the principle of the Wheatstone bridge in the construction of his range-finder.

(F. M. L.)

RANGER, HENRY WARD (1858– ), American artist, was born at Syracuse, New York, in January 1858. He became a prominent landscape and marine painter, much of his work being done in Holland, and showing the influence of the modern Dutch school. He became a National Academician (1906), and a member of the American Water Color Society. Among his paintings are, "Top of the Hill," Corcoran Gallery of Art, Washington, D.C.; and "East River Idyll," Carnegie Institute, Pittsburg.

Rangoon, the capital of Burma, situated on the left bank of the Hlaing or Rangoon river, 21 m. from the sea, in 16° 47' N. and 96° 13' E. In 1880 the city was detached from the main district, called Hanthawaddy, and formed into a separate district, with an area of 19 sq. m. Pop. (1901) 234,881, of whom just half were immigrants from India. Rangoon, from being a comparatively insignificant place, has within less than half a century risen to be the third seaport in British India, being surpassed only by Calcutta and Bombay in the volume of its trade. During the busy season of rice-export, which lasts from the end of December to the middle of May, the pool forming the port of Rangoon presents almost as crowded a scene as the Hugli at Calcutta. Rangoon has the double advantage of being situated near the sea and being served by a great river navigable for 900 m. behind it. The approach to the port is not difficult at any season of the year. With flat and shelving shores, the shoal-banks off the main mouths of the delta form the chief danger to shipping, and this is guarded against by a good service of lighthouses and lightships. For a length of seven or eight miles the river is from a mile to a mile and a quarter in breadth, so that there is plenty of accommodation for shipping. Here is concentrated the whole of the rich trade of the delta of the Irrawaddy. Great part of the river-frontage is occupied with rice-mills, tea & wharves and similar buildings. The rice exported from Rangoon in 1904–5 amounted to 28 million cwt. with a value of nearly 7 million sterling.

The city is dominated by the great golden pile of the Shwe Dagon pagoda, the centre of Burmese religious life. Rising to a height of 368 ft., this magnificent building is loftier than St. Paul's Cathedral in London, and is further elevated by the fact that it stands on an eminence that is itself 168 ft. above the level of the city. It is covered with pure gold from base to summit, and in every generation this gold is renewed by public subscription. Moreover, benefactions to this pagoda are one of the chief methods of acquiring religious merit among the Burmese. The pagoda itself has no interior. It is a solid stupa of brick, in the form of a cone, raised on a relic chamber; and the place of worship is the surrounding platform with a perimeter of nearly 1400 ft.

Though traditionally a site of great sanctity, Rangoon owes its first importance to its rebuilding in 1753 by Alompra, the founder of the Burmese monarchy, who gave it the present name of Yan Kon, "the end of the war." An English factory was opened here about 1790. On the outbreak of the first Burmese War, in 1824, it was taken by the British, but subsequently restored. It was captured a second time in 1852, and passed along with the province of Pegu into the hands of the British. It was destroyed by fire in 1851, and serious conflagrations occurred again in 1853 and 1855. Since the last devastation Rangoon has undergone considerable improvements. Until 1874, when the existing municipality was constituted, the administration was in the hands of the local government, which devoted itself to raising the centre of the town above the river level, providing land fit for building purposes from the original swamp, which was flooded at spring-tides, and making roads, bridges, culverts and surface drains. In 1892 was introduced the sewage system, which now includes 6 m. of mains, 22,000 ft. of gravitating sewers, 43 ft. of air mains and 44 Shone's ejectors. The water supply, drawn from the Victoria Lake, 5 m. distant, has recently been supplemented by an additional reservoir, 10 m. farther off. The city proper of Rangoon with the Kemmemide suburb is laid out on the block system, each block being 800 by 860 ft., intersected with regular streets. In the extensions to the east and west it has been decided to have no streets less than 50 ft. wide. The roads are still lighted by kerosene-oil lamps, but electric lighting is in contemplation. Electric tramways run to Pazundaung in one direction and to Alon and Kemmemide in the other, as well as to the foot of the Shwe Dagon Pagoda hill. Latterly the erection of masonry buildings, instead of plank houses, has been insisted on in the central portion of the city, with the result that fires have decreased in number. There are two large markets, or commons, which are used as military parade grounds and for racing, as well as for golf links and other purposes of amusement. There is a garden round the Phaye Museum, managed by the Agi-Horticultural Society, and an extremely pretty and well-kept garden in the cottages in the suburbs. Beyond these lie the Royal Lake and Dalhousie Park, with 160 acres of water and 205 acres of well-laid-out and well-timbered park land. Dalhousie Park has recently been greatly extended, and the new Victoria Park, declared open on the
occasion of the visit of the prince of Wales in 1806, is quite the finest in the East. There are two cathedrals, Church of England and Roman Catholic, and a Presbyterian church, besides the cantonment church buildings for worship. Religious buildings and lands, indeed, occupy an area in Rangoon out of all proportion to its size. Buddhists, Hindus, Mussulmans, Parsees, Armenians and Jews all own lands and pagodas, temples, mosques, churches and synagogues. The Buddhist monasteries, in particular, occupy wide spaces in very central portions of the town and cantonments. Burial-grounds are equally extensive, and exist in every direction in what were once the outskirts, but are now fast becoming central parts of the city. The chief educational institutions are the Government Rangoon college, the Baptist college and St John's college (S.P.G.). Besides the general hospital, a female hospital in connexion with the Dufferin Fund has recently been built, and there are hospitals for contagious diseases and for lepers in the suburbs. The staple industries are mills for husking rice and for sawing timber, and petroleum refineries. Carving in wood and ivory, and embossed silver work are also carried on. There are three municipal and eight private markets, which are being improved and extended. Everything, from sacking to jewelry, is sold in them. The introduction of pure water and the establishment of compulsory vaccination have greatly improved the health of Rangoon. But the death-rate is still high, due partly to the swampy nature of the outskirts of the city proper, and still more to the mortality among Hindu immigrants from the Madras presidency. The total rainfall in 1905 was 104.96 in. Rangoon is the head-quarters of a brigade in the Burma command of the Southern army.

RANGPUR, or RUPNORE, a town and district of British India, in the Rajshahi division of Eastern Bengal and Assam. The town is situated on the little river Ghaghat. Pop. (1901) 15,960. There are a high school, a normal school and an industrial school. The earthquake of the 12th of June 1897 destroyed many of the public buildings and diverted the drainage channels.

The District of Rangpur, with an area of 3403 sq. m., is one vast plain. The greater part of it, particularly towards the east, is inundated during the rains, and the remainder is traversed by a network of streams which frequently break through their sandy banks and plough for themselves new channels over the fields. The river system is constituted by the Brahmaputra and its tributaries, chief of which are the Tista, Dhara, Sankos and Dudh Kumar. The climate is generally malarious, owing to the numerous stagnant swamps and marshes filled with decaying vegetable matter. The annual rainfall averages 82 in. About three-fourths of the district is under continuous cultivation. Spare land can hardly be said to exist—even the patches of waste land yield a valuable tribute of reeds and cane. The staple crops are rice, oil-seeds, jute and tobacco. In 1901 the population was 2,154,181, showing an increase of 17.14% in the decade. Nearly two-thirds are Maharanis. The Eastern Bengal railway has two branches, one of which crosses the district to the Brahmaputra, and the other runs north towards Assam.

The tract comprised within the district of Rangpur was formerly the western outpost of the ancient Hindu kingdom of Kamrup, which appears to have attained its greatest power and prosperity under Raja Nilambar, who was treacherously overthrown by Ala-uddin Hosain of Bengal at the close of the 15th century. Rangpur passed to the East India Company in 1765 under the firm of the emperor Shah Alam. Since then a great number of changes have taken place in the jurisdiction, in consequence of which the district area has been much diminished.

RANJIT SINGH, MAHARAJA (1780-1839), native Indian ruler, was born on the 2nd of November 1780, the son of Sirdar Mahan Singh, whom he succeeded in 1792 as head of the Sukrabakhi branch of the Sikh confederacy. By birth he was only one of many Sikh barons and owed his rapid rise entirely to force of character and will. At the age of seventeen he seized the reins of government. He is said to have poisoned his mother, though it is more probable that he merely imprisoned her to keep her out of his way. At the age of twenty he obtained from Zaman Shah, the king of Afghanistan, a grant of Lahore, which he seized by force of arms in 1799. Subsequently he attacked and annexed Amritsar in 1802, thus becoming master of the two Sikh capitals. When Jaswant Rao Holkar took refuge in the Punjab in 1805, Ranjit Singh made a treaty with the British, excluding Holkar from his territory. Shortly afterwards acute difficulties arose between him and the British as to the Cis-Sutlej portion of the Punjab. It was Ranjit Singh's ambition to weld the whole of the Punjab into a single Sikh empire, while the British claimed the territory south of the Sutlej by right of conquest from the Mahrattas. The difference proceeded almost to the point of war; but at the last moment Ranjit Singh gave way, and for the future faithfully observed his engagements with the British, whose rising power he was wise enough to gauge. In 1808 Charles Metcalfe was sent to settle this question with Ranjit Singh, and a treaty was concluded at Amritsar on the 15th of April 1809. At this period a band of Sikh fanatics called "akalis" attacked Sir Charles Metcalfe's escort, and the steadiness with which the disciplined sepoyos repulsed them, so impressed the maharaja that he decided to change the strength of his army from cavalry to infantry. He organized a powerful force, which was trained by French and Italian officers such as Generals Ventura, Allard and Avitabile, and thus forged the formidable fighting instrument of the Khalsa army, which afterwards gave the British their hardest battles in India in the two Sikh wars. In 1810 he captured Multan after many assaults and a long siege, and in 1820 had consolidated the whole of the Punjab between the Sutlej and the Indus under his dominion. In 1823 the city and province of Peshawar became tributary to him. In 1833 when Shah Shuja, flying from Afghanistan, sought refuge at his court, he took from him the Koh-i-nor diamond, which subsequently came into the possession of the British crown. Though he disapproved of Lord Auckland's policy of substituting Shah Shuja for Dost Mahomed, he loyally supported the British in their advance on Afghanistan. Known as "The Lion of the Punjab," Ranjit Singh died of paralysis on the 27th of June 1839.

In his private life Ranjit Singh was self-sufficient, avuncular, drunken and immoral, but he had a genius for command and was the only man the Sikhs ever produced strong enough to bind them together. His military genius showed itself not so much in actual generalship as in the organization of his plans, the selection of his generals and his ministers, the tenacity of his purpose and the soundness of his judgment. The British were the one power in India that was too strong for him, and as soon as he realized that fact he was unwaveringly loyal to his engagements with them. His power was military aristocracy resting on the personal qualities of its founder, and after his death the Sikh confederacy gradually crumbled and fell to pieces through sheer want of leadership; and the rule of the Sikhs in the Punjab was by any completely as soon as it incurred the hostility of the British.

See Sir Lepel Griffin, Ranjit Singh (Rulers of India Series), 1892; General Sir John Gordon, The Sikhs, 1904; and S. S. Thorburn, The Punjab in Peace and War, 1904.
At Rome, as he said, he learned to see events from the inside. He wrote nothing but a critical examination of the story of Don Carlos, but he returned to Germany a master of his craft.

For a time Ranke was now engaged in an occupation of a different nature, for he was appointed editor of a periodical in which Friedrich Perthes designed to defend the Prussian government against the democratic press. Ranke, contemptuous in politics, as in history, of the men who warped facts to support some abstract theory, especially disliked the doctrinaire liberalism so fashionable at the time. He hoped, by presenting facts as they were, to win the adhesion of all parties. We need not be surprised that he failed; men desired not the scientific treatment of politics, but satire and invective. Exposed thus to attack, his weakness, if not his venality, was long an article of faith among the liberals. He did not satisfy the Prussian conservatives, and after four years the Historische Politische Blätter came to an end. Two-thirds of the matter had been contributed by the editor, and the two stout volumes in which the numbers were collected contained the best political thought which had for long appeared in Germany. For Ranke the failure was not to be regretted; the rest of his life was to be wholly devoted to that in which he excelled. During 1834-36 appeared the three volumes of his Die römischen Päste, ihre Kirche und ihr Staat im 16 und 17 Jahrhundert (Berlin, 1834-36, and many other editions), in form, as in matter, the greatest of his works, containing the results of his studies in Italy. Henceforth his name was known in all European countries; the English translation by Mrs Austin was the occasion of one of Macaulay's most brilliant essays. Before it was completed he had already begun the researches on which was based the second of his masterpieces, his Deutsche Geschichte im Zeitalter der Reformation (Berlin, 1839-47), a necessary pendant to his book on the popes, and the most popular of his works in his own country. In 1837 he became full professor at Berlin; in 1841 Frederick William IV., always ready to recognize intellectual eminence, appointed him Prussian historiographer. Stimulated by this, he brought out his Neun Bücher preussischer Geschichte (1847-48), a work which, chiefly owing to the nature of the subject, makes severe demands on the attention of the reader—he is the "Dryasdust" of Carlyle's Everdick; but in it he laid the foundation for the modern appreciation of the founders of the Prussian state. The nine books were subsequently expanded to twelve (Leipzig, 1874). He took no immediate part in the movements of 1848, but in the following years he drew up several memoranda for the king, whom he encouraged in his efforts to defend the character and identity of the Prussian state against the revolutionaries. Though never admitted into the inner circle of the king's associates, he found the king the most appreciative of readers and stimulating of companions, and the queen one of the most faithful of his friends; in biographical works and on other occasions he always defended the memory of the unfortunate monarch. A friend even more sympathetic he found in Maximilian II. of Bavaria, whom he advised in his expansive schemes for the promotion of learning and letters. In the quieter years that followed he wrote the third of his masterpieces, Französische Geschichte, vornemlich im 16 und 17. Jahrhundert (Stuttgart, 1855-61), which was followed by his Englische Geschichte, vornemlich im 16 und 17. Jahrhundert (1859-68). This, the longest of his works, added much to existing knowledge, especially as to the relations between England and the continent, but it lacked something of the freshness of his earlier books; he was over seventy when it was completed, and he was never quite at home in dealing with the parliamentary foundations of English public life. In his later years his small alert figure was one of the most distinguished in the society of Berlin, and every honour open to a man of letters was conferred upon him. He was ennobled in 1865, and in 1885 received the title of Excellenz. When the weakness of his eyes made it necessary for him to depend almost entirely on the service of readers and secretaries
in his eighty-first year he began to write the *Weltgeschichte* (9 vols., Leipzig, 1853-88). Drawing on the knowledge accumulated during sixty years, he had brought it down to the end of the 15th century before his death in Berlin on the 23rd of May 1886.

Ranke's other writings include *Zur deutschen Geschichte. Vom Religionsfrieden bis zum 30 jährigen Kriege* (Leipzig, 1868); *Geschichte Wollensteins* (Leipzig, 1869; 5th ed., 1896); *Abhandlungen und Versuche* (Leipzig, 1877); a new collection of these writings was edited by A. Dove and T. Wiedemann, Leipzig, 1888); *Aus dem Briefwechsel Friedrich Wilhelms IV. mit Bunsen* (Leipzig, 1873); *Die deutschen Mächte und der Fürstenbund. Deutsche Geschicht 1780-90* (1871-72); *Historisch-biographische Studien* (Leipzig, 1878); *Ursprung und Beginn der Revolutionskriege 1791-92* (Leipzig, 1875); and *Zur Geschichte von Oesterreich und Preussen zwischen den Friedensschlüssen zu Aachen und Hubertusburg* (Leipzig, 1875). He also wrote biographies of Frederick the Great and Frederick William IV for the *Allgemeine Deutsche Biographie*.

Ranke married, at Windermere, in 1843, Miss Clara Graves, daughter of an Irish barrister. She died in 1870, leaving two sons and a daughter.

At the time of his death Ranke was, not in his own country alone, generally regarded as the first of modern historians. It is no disparagement to point out that the recognition he obtained was due not only to his published work, but also to his success as a teacher. His public lectures, indeed, were never largely attended, but in his more private classes, where he dealt with the technical work of a historian, he trained generations of scholars. No one since Heyne has had so great an influence on German academical life, and for a whole generation the Berlin school had no rival. He took paternal pride in the achievements of his pupils, and delighted to see, through them, his influence spreading in every university. While his own work lay chiefly in more modern times, he trained in his classes a school of writers on German medieval history. As must always happen, it is only a part of his characteristics which they learnt from him, for his greatest qualities were incommunicable. The critical method which he has since become almost a formal system, aiming at scientific certainty, was with him an unexampled power, based on the insight acquired from wide knowledge, which enabled him to judge the credibility of an author or the genuineness of an authority; but he has made it impossible for any one to attempt to write modern history except on the "narratives of eye-witnesses and the most genuine immediate documents" preserved in the archives. From the beginning he was determined never to allow himself to be misled, in his search for truth, by those theories and prejudices by which nearly every other historian was influenced—Hegelianism, Liberalism, Romanticism, religious and patriotic prejudice; but his superiority to the ordinary passions of the historian could only be attained by those who shared his elevation of character. "My object is simply to find out how the things actually occurred." "I am first a historian, then a Christian," he himself said. In another way no historian is less objective, for in his great works the whole narrative is coloured by the quality of his mind expressed in his style. An enemy to all controversy and all violence, whether in act or thought, he had a serenity of character comparable only to that of Sophocles or Goethe. Apto minimize difficulties, to search for the common ground of unity in opponents, he turned aside, with a disdain which superficial critics often mistook for indifference, from the base, the violent and the common. As in a Greek tragedy, we hear in his works the echo of great events and terrible catastrophes; we do not see them. He also made it a principle not to relate that which was already well known, a maxim which necessarily prevented his works attaining a popularity with the unlearned equal to their reputation among historians. But no writer has surpassed him in the clearness and brevity with which he could sum up the characteristics of an epoch in the history of the world, or present and define the great forces by which the world has been influenced. His classicism led to his great limitations as an historian. He did not deal with the history of the people, with the growth of social problems—the dignity of history was to him a reality. He belonged to the school of Thucydides and Gibbon, not to that of Macaulay and Taine; he deals by preference with the rulers and leaders of the world, and he strictly limits his field to the history of the state, or, as we should say, political history; and in this he is followed by Seeley, one of the greatest of his adherents. The leader of modern historians, he was in truth a man of the *ancien régime*.

Many of Ranke's works have been translated into English. Among these are *Civil Wars and Monarchy in France*, by M. A. Garvey (1852); *History of England, principally in the 17th Century* (Oxford, 1875); *History of the Latin and Teutonic Nations, 1494-1514*, by F. A. Abeweith (1887) and again by C. R. Dennis (1893); *History of the Reformation in Germany*, by S. Austin (1845-47); *History of Servia and the Servian Revolution*, by Mrs. A. Kerr (1847); *Ferdinand I. and Maximilian II. of Austria, State of Germany after the Reformation*, by Lady Duff Gordon (1853); *Memoirs of the House of Brandenburg and History of Prussia during the 17th and 18th Centuries*, by Sir Alexander and Lady Duff Gordon (1849); and *History of the Popes during the 16th and 17th Centuries*, by S. Austin (1840; new ed., 1841 and 1847), by W. K. Kelly (1843), and by E. Foster (1847-53). A collected edition of Ranke's works in fifty-four volumes was issued at Leipzig (1868-90), but this does not contain the *Weltgeschichte*.

The chief events of Ranke's life and work see his own *Zur eigenen Lebensgeschichte*, edited by A. Dove (Leipzig, 1890); and the article by Dove in the *Allgemeine deutsche Biographie*. Also Winckler, *Leopold von Ranke. Lichtstrahlen aus seinen Werken* (1885); *Automatische, theoretische und praktische Thermodynamik*, by S. Carnot (1887); *Guglia, Leopold von Ranke's Leben und Werke* (Leipzig, 1893); M. Ritze, *Leopold von Ranke* (Stuttgart, 1896); Nalbandian, *Leopold von Ranke's Bildungsjahre und Geschichtsauffassung* (Leipzig, 1901); and Helmolt, *Leopold Ranke* (Leipzig, 1907).

**RANKINE, WILLIAM JOHN MACQUORN** (1820-1872), Scottish engineer and physicist, was born at Edinburgh on the 5th of July 1820, and completed his education in its university. He was trained as an engineer under Sir J. B. Macneill, working chiefly on surveys, harbours and railroads, and was appointed in 1855 to the chair of civil engineering in Glasgow, vacant by the resignation of Lewes Gordon, whose work he had undertaken to supervise. He was a voluminous writer on subjects directly connected with his chair, and, besides contributing almost weekly to the technical journals, such as the *Engineer*, brought out a series of standard textbooks on *Civil Engineering, The Steam-Engine and other Prime Movers, Machinery and Millwork*, and *Applied Mechanics*, which have passed through many editions, and have contributed greatly to the advancement of the subjects with which they deal. To these must be added his elaborate treatise on *Shipbuilding, Theoretical and Practical*. These writings, however, corresponded to but one phase of Rankine's immense energy and many-sided character. He was an enthusiastic and most useful leader of the volunteer movement from its beginning, and a writer, composer and singer of humorous and patriotic songs, some of which, as "The Three Foot Rule" and "They never shall have Gibraltar," became well known far beyond the circle of his acquaintance. Rankine was the earliest of the practical scientists who contributed to the development of the science of thermodynamics (q.v.) on the bases laid by Sadi Carnot and J. P. Joule respectively, and the author of the first formal treatise on the subject. His contributions to the theories of Elasticity and of Waves rank high among modern developments of mathematical physics, although they are mere units among the 150 scientific papers attached to his name in the Royal Society's *Catalogue*. The more important of these were collected and reprinted in a handsome volume (Rankine's *Scientific Papers*, London, 1881), which contains a memoir of the author by Prof. P. G. Tait. Rankine died at London on the 24th of December 1872.

**RANNOCH**, a district of north-west Perthshire, Scotland, partly extending into Argyllshire. It measures 32 m. E. and W. and from 10 to 12 m. N. and S. and is surrounded by the districts of Badenoch, Atholl, Breadalbane, Lorne and Lochaber. Much of it is wild, bleak and boggy, and, saving on the E., it is shut in by rugged mountains. The chief rivers are
the Tummel and the Ericht, and the principal lakes Loch Rannoch and Loch Lydach, or Laidon (about 6 m. long, 3 m. wide and 924 ft. above the sea). Loch Rannoch lies E. and W., measures 92 m. long by fully 1 m. broad, is 668 ft. above the sea, covers an area of nearly 7 ½ sq. m., and has a greatest depth of 440 ft. It receives the Ericht and many other streams, and discharges by the Tummel, draining a total area of 2433 sq. m. At the head of the lake is Rannoch Barracks, so named because it was originally built to accommodate a detachment of troops, under ensign (afterwards Sir) Hector Munro, stationed here to maintain order after the Jacobite rising of 1745. Two miles east is Carie, which was the residence of Alexander Robertson, 13th baron of Struan (1670-1749), the Jacobite and poet, who was “out” with Dundee (1689), Mar (1715) and Prince Charles Edward (1745), and yet managed to escape all punishment beyond self-imposed exile to France after the first two rebellions. Kinloch Rannoch, at the foot of the loch, is the principal place in the district, and is in communication by coach with Struan station (13 m. distant) on the Highland, and Rannoch station (6 m.) on the West Highland railway. Dugald Buchanan (1716-1768), the Gaelic poet, was school-master of the village for thirteen years, and a granite obelisk has been erected here in his memory.

**RANSOM** (from Lat. *redemption*, through Fr. *ransom*), the price for which a captive in war redeemed his life or his freedom, a town secured immunity from sack, and a ship was repurchased from her captors. The practice of taking ransoms arose in the middle ages, and had perhaps a connexion with the common Teutonic custom of commuting for crimes by money payments. It may, however, have no such historic descent. The desire to make profit out of the risks of battle, even when they were notoriously diminished by the use of armour, would account for it sufficiently. The right to ransoms was recognized by law. One of the obligations of a feudal tenant was to contribute towards paying the ransom of his lord. England was taxed for the ransom of Richard the Lion Hearted, France for King John taken at Poitiers, and Scotland for King David when he was captured at Durham. The prospect of gaining the ransom of a prisoner must have tended to diminish the fervour of medieval war, even when it did not reduce the fighting between the knights to a form of athletic sport in which the loser paid a forfeit. Readers of Froissart will find frequent mention of this decidedly commercial aspect of the chivalrous wars of the time. He often records how victors and vanquished arranged their “financing.” The mercenary views of the military adventurers were not disguised. Froissart repeats the story that the English “free companions” or mercenaries, who sold their services to the king of Portugal, grumbled at the battle of Aljubarrota in 1385, because he ordered their prisoners to be killed, and would not pursue the defeated French and Spaniards, whereby they lost lucrative captures. The ransom of a king belonged to the king of the enemy by whom he was taken. The actual captor was rewarded at the pleasure of his lord. King Edward III. paid over instalments of the ransom of the king of France to the Black Prince, to pay the expenses of his expedition into Spain in 1367. Occasionally, as in the notable case of Bertrand du Guesclin, the ransom of a valuable knight or leader would be paid by his own sovereign. Trade in ransoms became a form of financial speculation. Sir John Fastolf in the time of King Henry V. is said to have made a large fortune by buying prisoners, and then screwing heavy ransoms out of them by ill-usage. The humane influence of ransoms was of course confined to the knights who could pay. The common men, who were too poor, were massacred. Thus Lord Grey, Queen Elizabeth's lord deputy in Ireland, spared the officers of the Spaniards and Italians he took at Smerwick, but slaughtered the common men. Among the professional soldiers of Italy in the 15th century the hope of gaining ransom tended to reduce war to a farce. They would not lose their profits by killing their opponents. The disuse of the practice was no doubt largely due to the discovery that men who were serving for this form of gain could not be trusted to fight seriously.

Instances in which towns paid to avoid being plundered are numerable. So late as the war in the Peninsula, 1809-14, it was the belief of the English soldiers that a town taken by storm was liable to sack for three days, and they acted on their conviction at Ciudad Rodrigo, Badajoz, and San Sebastian. It was a question whether ransoms paid by merchant ships to escape war or were not among the *commercia belli*. In the early 18th century the custom was that the captain of a captured vessel gave a bond or “ransom bill,” leaving one of his crew as a hostage or “ransomer” in the hands of the captor. Frequent mention is made of the taking of French privateers which had in them ten or a dozen ransomers. The owner could be sued on his bond. At the beginning of the Seven Years' War ransoming was forbidden by act of parliament. But it was afterwards at least partially recognized by Great Britain, and was generally allowed by other nations. In recent times—for instance in the Russo-Japanese War—no mention was made of ransoms, and with the disappearance of privateering, which was conducted wholly for gain, it has ceased to have any place in war at sea, but the contributions levied by invading armies might still be accurately described by the name.

**RANTERS**, an Anabaptian and spiritualistic English sect in the time of the Commonwealth, who may be described as the dregs of the Seeker movement. Their central idea was pantheistic, that God is essentially in every creature, but though many of them were sincere and honest in their attempt to express the doctrine of the Divine immanence, they were in the main unable to hold the balance. They denied Church, Scripture, the current ministry and services, calling on men to hearken to Christ within them. Many of them seem to have rejected a belief in immortality and in a personal God, and in many ways they resemble the Brethren of the Free Spirit in the 15th century. Their vague pantheism landed them in moral confusion, and many of them were marked by fierce fanaticism. How far the accusation of lewdness brought against them is just is hard to say, but they seem to have been a really serious peril to the nation. They were largely recruited from the common people, and there is plenty of evidence to show that the movement was widespread. The Ranters came into contact and even rivalry with the early Quakers, who were often unjustly associated with them. The truth is that the positive message of the Friends helped to save England from being overrun with Rantersim. Samuel Fisher, a Friend, writing in 1653, gives a calm and instructive account of the Ranters, which with other relevant information, including Richard Baxter's rather hysterical attack, may be read in Rufus M. Jones's *Studies in Mystical Religion* (1900), xix. In the middle of the 17th century the name was often applied to the Primitive Methodists, with reference to their crude and often noisy preaching.

**RANUNCULACEAE**, in botany, a natural order of Dicotyledons belonging to the subclass Polytelatae, and containing 27 genera with about 900 species, which are distributed through temperate and cold regions but occur more especially beyond the tropics in the northern hemisphere. It is well represented in Britain, where 11 genera are native. The plants are mostly herbs, rarely shrubby, as in *Clematis*, which have slender leaf-stalks, with alternate leaves, opposite in *Clematis*, generally without stipules, and flowers which show considerable variation in the number and development of parts but are characterized by free hypogynous sepals and petals, numerous free stamens, usually many free one-celled carpels (fig. 2) and small seeds containing a minute straight embryo embedded in a copious endosperm. The parts of the flower are generally arranged spirally on a convex receptacle. The fruit is one-seeded, an achene (fig. 3), or a many-seeded follicle (fig. 4), rarely, as in *Actaea*, a berry.
The order falls into several well-defined tribes which are distinguished by characters of the flower and fruit; all are 

represented among British native or commonly grown garden plants.

Tribe I. *Paonieae*, peony group, are mostly herbs with deeply cut leaves and large solitary showy flowers in which the parts are spirally arranged, the sepals, generally five in number, passing gradually into the large coloured petals. The indefinite stamens are succeeded by 2–5 free carpels which bear a double row of ovules along the ventral suture. Honey is secreted by a ring-like swelling round the base of the carpels, which become fleshy or leathery in the fruit and disperse along the ventral suture. There are only three genera, the largest of which, *Paeonia*, occurs in Europe, temperate Asia and western North America. *P. officinalis* is the common peony.

Tribe II. *Helleboraeae* are almost exclusively north temperate or subarctic; there are 15 genera, several of which are represented in the British flora. The plants are herbs, either annual, e.g. *Nigella* (love-in-a-mist), or perennial by means of a rhizome, as in *Aconitum* or *Erantis* (winter aconite). The leaves are simple, as in *Caltha*, but more often palmately divided as in hellebore (fig. 6), aconite (fig. 5) and larkspur. The flowers are solitary (*Erantis*) or in cymes or racemes, and are generally regular as in *Caltha* (king-cup, marsh marigold), *Trollius* (globe-flower), *Helleborus*, *Aquilegia* (columbine); sometimes medianly zygomorphic as in *Aconitum* (monkshood, aconite) and *Delphinium* (larkspur). The carpels, generally 3 to 5 in number, form in the fruit a many-seeded follicle, except in *Actaea* (baneberry), where the single carpel develops to form a many-seeded berry, and in *Nigella*, where the five carpels unite to form a five-chambered ovary. There is considerable variety in the form of the floral envelopes and the arrangement of the parts. The outer series of sepals, generally five in number, is generally white or bright-coloured, serving as an attraction for insects, especially bees, as well as a protection for the rest of the flower. Thus in *Caltha* and *Trollius* the sepals form a brilliant golden-yellow cup or globe, and in *Erantis* a pale yellow star which contrasts with the green involucre of bracts immediately below it; in *Nigella* they are blue or yellow, and also coloured in *Aquilegia*. In Hellebore the greenish sepal persist till the fruit is ripe. *Aconitum* and *Delphinium* differ in the irregular development of the sepal.

The posterior sepal being distinguished from the remaining four by its helmet-shape (*Aconitum*) or spur (*Delphinium*). In *Caltha* there are no petals, but in the other genera there are honey-secreting and storing structures varying in number and in form in the different genera. In *Trollius* they are long and narrow with a honey-secreting pit at the base, in *Nigella* and *Helleborus* (fig. 7) they form short-

![Fig. 2.-Ranunculus arvensis. Carpel in longitudinal section. (After Baillon, enlarged.)](image1)

![Fig. 3.—Single follicle showing dehiscence by the ventral suture.](image2)

![Fig. 4.—Fruit of Columbine (Aquilegia) formed of five follicles.](image3)

Fig. 7.—*Helleborus niger*, 1, vertical section of flower; 2, nectary, side and front view (nat. size); 3, stalked pitchers, in *Aquilegia* they are large and coloured with a showy petal-like upper portion and a long basal spur in the tip of which is the nectary. In *Delphinium* they are also spurred, and in *Aconitum* form a spur-like sac on a long stalk (fig. 5). The parts of the flower are generally arranged in a spiral (acyclic), but are sometimes hemispheric, the perianth forming a wheel as in winter aconite; rarely is the flower cyclic, as in *Aquilegia* (fig. 9) where stalked pitchers, in *Aquilegia* they are large and coloured with a showy petal-like upper portion and a long basal spur in the tip of which

![Fig. 8.—Part of the flower of Aconite (Aconitum Napellus), showing two irregular horn-like petals p, supported on grooved stalks k. These serve as nectaries.](image4)

![Fig. 9.—Floral diagram of Columbine (Aquilegia) showing regular cyclic arrangement.](image5)

cy's, and in *Aquilegia* (fig. 8) they are irregular horn-like petals supported on grooved stalks. These serve as nectaries. The parts throughout are arranged in alternating whorls. In *Caltha*, where there are no petals, honey is secreted by two shallow depressions on the side of each carpel.

Tribe III. *Anemonoeae*, with 8 genera, are chiefly north temperate, arctic and alpine plants, but also pass beyond the tropics to the southern hemisphere. They differ from the two preceding tribes in the numerous carpels, each with only one ovule, forming a fruit of numerous achenes. They are annual or perennial herbs, erect as in *Anemone*, *Thalictrum* (meadow-rue) and many buttercups, or creeping as in *Ranunculus repens*; the section *Batraichem* of the genus *Ranunculus* (q.v.) contains aquatic plants with submerged or floating stems and leaves. The flowers are solitary, as in *Anemone Pulsatilla* (*Pasque flower*) and the wood anemone, or cymose as in species of *Ranunculus*, or in rayed or panicled as in *Thalictrum*. The parts are spirally arranged throughout as in *Myosurus* (mouse-tail), where the very numerous carpels are borne on a much elongated receptacle, or *Adonis* (pheasant's eye), or the perianth is whorled as in *Anemone* and *Ranunculus*. In *Anemone* there is a whorl of foliate leaves below the flower, as in *Erantis*. In *Anemone* and *Thalictrum* there is only one series of perianth leaves, which are petaloid and attractive in *Anemone* where honey is secreted by modified stamens, as in *A. Pulsatilla*, or, as in *A. nemorosa* (wood anemone), there is no honey and the flower is visited by insects for the sake of the pollen; in *Thalictrum* the perianth is greenish or
slightly coloured and the flower is wind-pollinated (T. minus) or visited for its pollen. In Ranunculus and Adonis a calyx of green protective sepals is succeeded by a corolla of showy petals; in *Ranunculus* (fig. 10) there is a basal honey-secreting gland which is found in *Adonis* also. In *Ranunculus* the calyx bears the persistent naked or bearded style which aids in dissemination; the same purpose is served by the prickles on the achenes of *Adonis*. The stamens are inserted below the petals and are somewhat unequal; the filaments bear glandular hairs; the anthers are dehiscing by longitudinal slits.

**Tribe IV. Clematideae** embrace the genus *Clematis* (p. xvi), characterized by its shrubby, often climbing habit, opposite leaves and the flowers, not usually terminal, in the order of the achenes, in the axils of the sepal-like bracts. The flowers have five stamens with filiform anthers and, in the same order, five petals. The fruit is a two- or three-valved capsule.

**RANUNCULUS**, familiarly known as "buttercup," or crow-foot, is a characteristic type of the botanical order Ranunculaceae. The Lat. name, which means a little frog or tadpole (dim. of ranus, [frog]), was also given to a medicinal plant, which has been identified by some with the crow-foot. The Ranunculi are more or less acid herbs, sometimes with fleshy root-fibres, or with the base of the stem dilated into a kind of tuber (*R. bulbosus*). They have tufted or alternate leaves, dilated into a sheath at the base, and, very generally, but not universally, deeply divided above. The flowers are solitary, or in loose cymes, and are remarkable for the number and distinctness (freedom from union) of their parts. Thus there are five sepals, as many petals, and numerous spirally arranged stamens and carpels. The petals have a little pit or honey-gland at the base, which is interesting forshowing the more fully developed tubular petals of the nearly allied genera *Aconitum* and *Helleborus*. The fruit is a head of "achenes"—dry, one-seeded fruits. The genus contains a large number of species (about 250) and occurs in most temperate countries in the northern and southern hemispheres, extending into arctic and antarctic regions, and appearing on the higher mountains in the tropics. About twenty species are natives of Great Britain. *R. acris*, *R. repens*, *R. bulbosus*, are the common buttercups. *R. arvensis*, found in cornfields, has smaller pale yellow flowers and the achenes covered with stout spines. *R. Lingua*, spearwort, and *R. Flammula*, lesser spearwort, grow in marshes, ditches and wet places. *R. Ficaria* is the pilewort or lesser celandine, an early spring flower in pastures and waste places, characterized by having heart-shaped leaves and clusters of club-shaped roots. The section *Batrachium* comprises the water-buttercups, denizens of pools and streams, which vary greatly in the character of the foliage according as it is submerged, floating or aerial, and when submerged varying in accordance with the depth and strength of the current. The ranunculus of the florist is a cultivated form of *R. acris*, a native of the Levant, remarkable for the range of coloured flowers (yellow to purplish black) and for the regularity with which the stamens and pistils are replaced by petals forming double flowers. *R. asiaticus* is one of the older florists' flowers, which has sported into numberless varieties, but was formerly held in much greater esteem than it is at the present time. According to the canons of the florists, the flowers, to be perfect, should be of the form of two-thirds of a ball, the outline forming a perfect circle, with the center close to the petals smooth-edged, the colour dense, and the marking uniform.

The ranunculus requires a strong and moist soil, with a fourth of rotten dung. The soil should be from 18 in. to 2 ft. deep, and at about 5 in. below the surface there should be placed a stratum 6 or 8 in. thick of two-year-old rotten cow-dung, mixed with earth, the earth above this stratum, where the roots are to be placed, being perfectly free from fresh dung. The tubers are planted in rows 5 or 6 in. apart, and 3 or 4 in. apart in the rows, the turban sorts in October, the more choice varieties in February. They should be so close that the foliage may cover the surface of the bed. The autumn-planted rooted plants may be set in the last-mentioned periods from semi-doubtful sorts, which are often of themselves very beautiful flowers. It is generally sown in boxes in autumn or spring. The young plants thus raised flower often in the second, and always in the third year.

Of the various varieties, which are very showy for the borders, are a few of positive colours, as scarlet, yellow, brown, carmine, and white. The florists' varieties have been bred from the Persian *R.* which is more round-leaved.

Other species known in gardens are *R. aconitifolius* (white bachelor's buttons), with leaves recalling aconite, and white flowers; the double-flowered form is known in gardens as fair maids of France or fair maids of Kent. A double-flowered form of *R. acris* is grown under the name yellow bachelor's buttons. *R. bulbosus* also has a pretty double-flowered variety. Of dwarfer interesting plants there are *R. alpestris*, 4 in., white; *R. granatus*, 6 in. to 10 in., yellow; *R. parrannia*, 6 in., white; and *R. rufulae* (white), 4 to 6 in. wide, having orange centre. Of the taller kinds mention may be made of *R. corytoseifolius*, a fine buttercup, 3–5 ft. high, from Tenerife, and hardy in the mildest parts of Britain; and *R. hyalina*, known as the New Zealand buttercup, which flowers well in water, is particularly high, with large petalaceous leaves an inch wide, and with waxy white flowers about 4 in. across. It is not quite hardy, and even under the best conditions is a difficult plant to grow well.

**RAO, SIR DINKAR** (1819–1896), Indian statesman, was born in Ratnagiri district, Bombay, on the 20th of December 1819, being a Chitpavan Brahmin. At fifteen he entered the service of the Gwalior state, in which his ancestors had served. Rapidly promoted to the responsible charge of a division, he displayed unusual talents in reorganizing the police and revenue departments, and in reducing chaos to order. In 1851 Dinker Rao became dewan. The events which led to the British victories of Maharajpur and Panniar in 1844 had filled the state with mutinous soldiers, ruined the finances, and weakened authority. With a strong hand the dewan suppressed disorder, abolished ruinous imposts, executed public works, and by a reduction of salaries, including his own, turned a deficit into a surplus. When the contingent mutinied in 1857, he never wavered in loyalty; and although the state troops also mutinied in June 1858 on the approach of Tantia Topi, he adhered to the British and later served in the 51st and 1st Madras regiments as a Captain. After the restoration of order he remained minister until December 1859. In 1873 he was appointed guardian to the minor Rana of Dholpur, but soon afterwards he resigned, owing to ill-health. In 1875 the viceregy selected him as a commissioner, with the Maharajas Sindhia and Jaipur, and three British colleagues, to try the Gaekwar of Baroda on a charge of attempting to poison the British resident. He also served in the legislative council of India, and was frequently consulted by viceroys on difficult questions. An estate was conferred upon him, with the hereditary title of Raja, for his eminent services, and the decoration of K.C.S.I. He died on the 9th of January 1896. No Indian statesman of the 19th century gained a higher reputation, yet he only commenced the study of English at the age of forty, and was never able to converse fluently. He devoted himself to the abolition of regiments and to the resented social reforms; he kept aloof from the Indian Congress, and he had received no training in British administration.

**RAO, SIR T. MADHAVA** (1828–1891), Indian statesman, was born at Combaconum in Madras in 1828. Madhava Rao created a new type of minister adapted to the modern requirements of a progressive native state, and he justified it upon the old stock. He linked the past with the present, using the advantages of heredity, tradition and conservatism to effect reforms in the public administration and in Indian society. Sprung from a Mahatta Brahmin stock long settled at Tanjore, the son of a dewan of Travancore, he was educated in the strictest tenets of his sacred caste. But he readily imbued the new spirit of the age. To mathematics, science and astronomy he added a study of English philosophy and international law, and a taste for art...
RAOUL DE CAMBRAI—RAPALLO

and pictures. Although a devout student of the Shastras, he advocated female education and social reform. Refusing to cross the sea and so break caste by appearing before a parliamentary commission, he yet preached religious toleration. A patron of the Indian Congress, he borrowed from the armoury of British administration every reform which he introduced into the native states. He was respected alike by Europeans and natives, and received titles and honours from the British government. As tutor of the maharaja of Travancore, and then as revenue officer in that state, he showed firmness and ability, and became diwan or prime minister in 1837. He found the finances disorganized, and trade cramped by monopolies and oppressive duties. He co-operated with the Madras government in carrying out reforms, and when his measures led to misunderstandings with the maharaja, he preferred honourable resignation to retention of a lucrative office in which he was powerless for good. In 1872 he was engaged at Indore in laying down a plan of reform and of public works which he bequeathed to his successor, when a grave crisis at Baroda demanded his talents there. The Gaekwar had been deposed for scandalous misrule, and an entire reorganization was needed. Aided by Phillip Melvill, his mansar, Raoul accepted the commission, and enforced the desired reforms, which were carried out by other officials, privileged landowners, and grasping contractors who had long ruined Baroda. He wrote able minutes defending the rights and privileges of the Gaekwar from fancied encroachment, and justifying the internal reforms which he introduced. He resigned office in 1882, and in his retirement devoted his leisure to reading and writing upon political and social subjects. He died on the 4th of April 1891.

RAOUL DE CAMBRAI, the name of a French chanson de geste. The existing romance is a 13th-century recension of a poem by a trouvère of Laon called Bertholais, who professed to have witnessed the events he described. It presents, like the other provincial geste of Garin le Lohéren, a picture of the devastation caused by the private wars of the feudal chiefs. A parallel narrative, obviously inspired by popular poetry, is preserved in the chronicle of Walsort (ed. Achery, Spicilegium, ii. p. 100 seq.), and probably corresponds with the earlier recension. Raoul de Cambrai, the posthumous son of Raoul Taillefer, count of Cambrai, by his wife Alais, sister of King Louis (1137-1180), whose father and grandfather, together occupied the fief of Vermandois, which was the natural inheritance of the four sons of Herbert, lord of Vermandois. On King Louis’s refusal, he proceeded to war. The chief hero on the Vermandois side was Bernier, a grandson of Count Herbert, who, driven into opposition by the fate of his mother, burned with the nuns in the church of Origny. Bernier eventually slew the terrible Raoul in single fight, but in his turn was slain, after an apparent reconciliation, and the blood-feud descended to his sons. The date of these events is exactly ascertainable. Hodoard (Annales, Anno 943) states that Count Herbert died in that year, and was buried by his sons at St Quentin, that when they learnt that Raoul, son of Raoul de Gouy, was about to invade their father’s territory, they attacked him and put him to death. The identity of other of the personages of the story has also been fixed from historical sources. The second part of the poem, of which Bernier is the hero, is of later date, and bears the character of a roman d’aventures.

See Li Romains de Raoul de Cambrai et de Bernier, ed. E. le Glay (Parıer, 1870); Memoires de la Société de Cambrai, ed. P. Meyer and A. Longnon (Soc. des anci. textes fr., Paris, 1882); J. M. Ludlow, Popular Épics of the Middle Ages (London and Cambridge, 1865); H. Gröber, Grundriss d. roman. Phil. (ii. pp. 567 seq.).

RAOUl ROCETTE, DÉSIRÉ (1790-1854), French archaeologist, was born on the 9th of March 1790 at St Amand in the department of Cher, and received his education at Bourges. He was made professor of history in the Collège de Louis-le-Grand at Paris (1813) and in the Sorbonne (1817). His Histoire critique de l’établissement des colonies grecques (4 vols., 1815) is now out of date. He was superintendent of antiquities in the Bibliothèque at Paris (1810-48), and professor of archaeology at the Bibliothèque (from 1826), a result of which may be seen in his Cours d’archéologie (1828). In 1829 appeared his Monuments inédits, a work of great value at the time. Still valuable are his Peintures inédits (1836) and his Peintures de Pompâi (1844). He contributed to the Annales of the Roman Institute, the Journal des savants and the Académie des inscriptions. At his death on the 3rd of July 1854 Raoul Rochette was perpetual secretary of the Academy of Fine Arts and a corresponding member of most of the learned societies in Europe.

RAOUL, FRANÇOIS MARIE (1830-1901), French chemist, was born at Fournes, in the Département du Nord, on the 10th of May 1830. He became aspirant répétiteur at the lycée of Rheims in 1855, and after holding several intermediate positions was appointed in 1862 to the professorship of chemistry in Sens lycée, where he prepared the thesis on electromotive force which gained him his doctor’s degree at Paris in the following year. In 1867 he was put in charge of the chemistry classes at Grenoble, and three years later he succeeded to the chair of chemistry, which he held until his death on the 1st of April 1901. Raoul’s earliest researches were physical in character, being largely concerned with the phenomena of voltaic current and of the chemistry of light and of the electrically determined chemical solutions engaged his attention. But his name is best known in connexion with the work on solutions, to which he devoted the last two decades of his life. His first paper on the depression of the freezing-points of liquids by the presence of substances dissolved in them was published in 1878; and continued investigation and experiment with various solvents, such as benzene and acetic acid, in addition to water, led him to believe in a simple relation between the molecular weights of the substances and the freezing-point of the solvent, which he expressed as the ‘loi générale de la congélation’, that if one molecule of a substance be dissolved in 100 molecules of any given solvent, the temperature of solidification of the latter will be lowered by 0.63° C. (See, however, the article SOLUTION.) Another relation at which he worked was that the diminution in the vapour-pressure of a solvent, caused by dissolving a substance in it, is proportional to the molecular weight of the substance dissolved—at least when the solution is dilute. These two generally hold only when the corresponding molecular weights of substances, but have also been utilized by J. H. van’t Hoff and W. Ostwald, among other chemists, in support of the hypothesis of electrolytic dissociation in solutions. An account of Raoul’s life and work was given by Professor van’t Hoff in a memorial lecture delivered before the London Chemical Society on the 26th of March 1902.

RAOUx, Jean (1677-1734), French painter, was born at Montpellier in 1677. After the usual course of training he became a member of the Academy in 1717 as an historical painter. His reputation had been previously established by the credit of decorations executed during his three years in Italy on the palace of Giustiniani Solini at Venice, and by some easel paintings, the Four Ages of Man (National Gallery), commissioned by the grand prior of Vendôme. To this latter class of subject Raoux devoted himself, nor did he even paint portraits except in character. The list of his works is a long series of sets of the Seasons, of the Hours, of the Elements, or of those scenes of amusement and gallantry in the representation of which he was immeasurably surpassed by his younger rival Watteau. After his stay in England (1720) he lived much in the Temple, where he decorated several rooms. He died in Paris in 1734. His best pupils were Chevalier and Montdidier. His works, of which there is a poor specimen in the Louvre, were much engraved by Poilly, Moyreau, Dupuis, &c.

RAPALLO, a seaport and winter resort of Liguria, Italy, in the province of Genoa. Pop. (1901) 5,839 (town); 10,343 (commune). It occupies a beautiful and well-sheltered situation on the east side of the Gulf of Rapallo, 18½ m. E. by S. from Genoa by rail. It has a fine church, a medieval castle (now used as a prison) and a Roman Bridge, known as “Hannibal’s Bridge.” On the hills above the town is situated the
church and abbey of the Madonna de Montallegra, whose miraculous picture attracts pilgrims from all parts of Italy. Olives and other fruit are grown, and a brisk trade is done in olive oil. A mile to the south is Santa Margherita Ligure (pop. 7031), another winter resort, with a large 16th-century church. Both places are also frequently sought for sea-bathing in summer. Lace is made, while the men go in May to the coral fisheries off the Sardinian coast. To the south again is the small seaport of Portofino (the Roman Portus Delphini) under the south-east extremity of the promontory of Portofino (190 ft.). On the way from S. Margherita to Portofino is the suppressed monastery of Cervara, in which Francis I. of France was confined after the battle of Pavia on his way to Madrid. At all these places are beautiful villas.

RAPE (Lat. rapum or rapa, turnip), in botany.—Several forms of plants included in the genus Brassica are cultivated for the oil which is present in their ripe seeds. The one most extensively grown for this purpose is known as colza, rape or coleseed, in Germany as Raps (Brassica napus, var. oleifera): its seeds contain from 30 to 45% of oil. The leaves are glaucous and smooth like those of a swede turnip. For a seed-crop rape is sown in May or early June, and is accord-

ingly a favourite crop in the ten lands of England, and on recently reclaimed moors and moors elsewhere. Its growth is greatly stimulated by the ashes resulting from the practice of paring and burning. Its highly nutritious leaves and stems are usually consumed by folding the sheep upon it where it grows, there is no green food upon which they fatten faster. Occasionally it is carried to the homestead, and used with other forage in carrying out the system of soiling cattle.

The wild form Brassica campestris, the wild coleseed, colza or kohlsaat, of the fields of England and many parts of Europe, is sometimes cultivated on the European continent for its seed, which, however, is inferior in value to rape as an oil-yielding product. In addition to the previously mentioned rape, a variety of another species (or subspecies) of Brassica, namely, Brassica rapa, var. oleifera (Rübsen in Germany), is grown for its oil-yielding seeds. The leaves in a young state are not glaucous, but sap-green in colour, and rough, being very similar to those of the turnip, to which the plant is closely related. Both winter and summer varieties are grown; they are rarely cultivated in Britain. The oil is similar to that in the true colza seeds but the plants do not yield so much per acre as the latter: they are, however, harder and more adapted for cultivation on poor sandy soils.

RAPE (from Lat. rapere, to seize), in law, the crime of having carnal knowledge of a woman by a man, not her husband, forcibly and unlawfully against her will. Under the Mosaic law, rape was punished with death, if the damsel was betrothed to another man, and with a fine of fifty shekels if not so betrothed, while in this case, also, she was to be the wife of the ravisher all the days of his life (Deut. xxii. 25). The Roman civil law punished rape with death and confiscation of goods (Cod. L. IX. tit. 132). In England, under the Saxon law—adopted, probably, from a Teutonic code—death was also the penalty, but under the Normans this was changed to the loss of both eyes and castration; this punishment remained in force until after the time of Bracton (de Coram, f. 147). The statute of Westminster I. (1275) reduced the offence to a trespass, with a penalty of two years' imprisonment and a fine at the king's will. This lenity, it is said, produced terrible consequences, and, accordingly, the statute of Westminster II. (1285) again declared the offence a felony, with, however, benefit of clergy. This was the state of the law when until 1575, when the punishment was made more severe by taking away the benefit of clergy. The offence remained capital until the Offences against the Person Act 1861, by which and subsequent amending acts it is now regulated. The present punishment is penal servitude for life or for not less than three years or imprisonment with or without hard labour for not over two years.

The law of England (differing in this respect from the civil law) regards as immaterial whether the woman is chaste or unchaste, married or single, provided the offence has been committed forcibly and without her consent. The offence is complete if consent is extorted by means of threats of death or immediate bodily harm, by force or by false pretences, or by the intimidation of some person, such as the impersonation of a woman's husband (Criminal Law Amendment Act 1885).

Since the passing of the Criminal Law Amendment Act 1885, rape is a felony, entailing the same punishment as rape, to have carnal knowledge of a girl under 13 years, whether she consent or not. Between 13 and 16 years of age it is a criminal offence punishable by two years' imprisonment, whether consent is given or not. If she consents, and if there be solicitation; but if the jury is satisfied that the person charged has reasonable cause to believe the girl to be over 16 years, the accused is entitled to be acquitted. Prosecution must be within three months of the offence. The accused is not entitled to a discharge or matter with justifiable, for instance, to facilitate the accomplishment of the crime, is an offence punishable by two years' imprisonment. On indictment for rape there may be an acquittal on the actual charge, but a conviction either of the attempt or of an indecent assault.

In New York, Colorado and Kansas it is as high as 18 years.

The essential facts to be proven in order to constitute this crime are the same as in England, but in many of the states the uncorroborated evidence of the woman is sufficient to sustain a conviction. This is so in California, Arizona, Idaho, Missouri, Kentucky, Michigan, Illinois, Oklahoma, &c. (1894; Brenton v. Territory, 78 Pac. Rep. 83). In New York corroboration is required (Penal Code §283). In Nebraska also evidence corroborating the prosecutrix is necessary (1897; Burk v. State, 112 N.W. Rep. 573). In Texas it is no defence for accused to prove that he believed the prosecutrix to be over 15 years of age, the age of consent 1897; Robertson v. State, 102 So. W. Rep. 112, and the crime is punishable with death 1903; Reym v. State, 112 So. W. Rep. 35), as also apparently it is in the Indian country (U.S. v. Partello, 48 Fed. R. 670 U.S. Rev. Stats. §§354, also in Alabama [Criminal Code, §5444].
The principal uses of rape oil are for lubrication and lighting; but since the introduction of mineral oils for both these purposes the importance of rape has considerably decreased. It is but little employed in soap-making, as it saponifies with difficulty and yields only a poor and resinous soap. In Germany it is very considerably used as a salad oil under the name of Schmalzöl, being for that purpose freed from its biting taste by being mixed with starch, heated till the starch is carbonized, and filtered after the oil has cooled. The offensive smell is removed by treatment with a small proportion of sweet spirit of nitre (nitrous ether). In the East Indies rape oil and its equivalents, known under various names, are the most important oils for native use. The latter is largely consumed as food instead of ghee, or "metah" or sweet oil, but for all other purposes the same substance is known as "kurrah" or bitter oil. Most natives prefer it for the preparation of their curries and other hot dishes. Rape oil is the subject of extensive adulteration, principally with the cheaper hemp and linseed oils, and mineral oils can be most conveniently detected, first by taste and next by saponification, resin oil and mineral oil remaining unsaponifiable. Hemp oil gives a greenish soap, while rape oil yields a soap with a yellow tinge. With respect to the use and meaning of rape, cotton, hemp and linseed oils are classified as acidic, nitrous, and other reagents rape oil gives also characteristic colorations; but these are modified according to the degree of purity of the oil itself. The presence of sulphur in rape and other cruciferous oils also affords a ready means for their identification. Lead plaster (emplastrum lithargyri) boiled in rape oil dissolves, and, sulphide of lead being formed, the oil becomes brown or black. Other lead compounds give the same black coloration from the formation of sulphide.

RAPE (Hebrew יְפָא, "God helps"), an angel who in human disguise and under the name of Azarias ("Yahweh helps") accompanies Tobias in his adventurous journey and conquers the demon Asmodeus (Book of Tobit). He is said (Tob. xii. 15) to be "one of the seven holy angels [archangels] which present the prayers of the saints and go in before the glory of the Holy One." In the Book of Enoch (c. x.) Raphael is described as one of the spirits of men, and it is his business to "heal the earth which the angels have defiled." In later Midrash Raphael appears as the angel commissioned to put down the evil spirits that vexed the sons of Noah with plagues and sicknesses after the Flood, and he it was who taught men the use of simples and furnished materials for the "Book of Noah," the earliest treatise on materia medica.

RAPHAEL SANZIO (1483-1520), the great Italian painter, was the son of Giovanni Sanzio or Santi, a painter of some repute in the ducal city of Urbino, situated among the Apennines on the borders of Tuscany and Umbria. For many years both before and after the birth of Raphael (6th of April 1483) the city of Urbino was one of the chief centres in Italy of intellectual and artistic activity, thanks to its highly cultured rulers, Duke Federigo II. of Montefeltro and his son Guidobaldo, who succeeded him in 1482, the year before Raphael was born. Giovanni Santi was a welcome guest at this miniature but splendid court, and the rich treasures which the palace contained, familiar to Raphael from his earliest years, were a very important item among the various influences which fostered his early love for art. It may not perhaps be purely fanciful to trace Raphael's boyish admiration of the oil-paintings of Jan Van Eyck and Justus of Ghent in the miniature-like care and delicacy with which some of his earliest works, such as the "Apollo and Marsyas," were executed.

Though Raphael lost his father at the age of eleven, yet to him he certainly owed a great part of that early training which enabled him to produce paintings of apparently mature beauty when he was scarcely twenty years of age. The altar-piece painted by Giovanni for the church of Gradara, and a fresco, now preserved in the Santi house at Urbino, are clearly prototypes of some of Raphael's most graceful achievements.

1 See Pungileoni, Elogio Storico di Raffaello (Urbino, 1829); for a valuable account of Raphael's family and his early life, see also 1d., Vita di Gio. Santi (Urbino, 1822), and Campori, Notizie e Documenti per la Vita di Gio. Santi e di Raffaello (Modena, 1870).
2 See an interesting account of the court of Urbino by Delaborde, Études sur les B. Arts... en Italie (Paris, 1864), vol. i. p. 145.
3 The house of Giovanni Santi, where Raphael was born, still exists at Urbino in the Contrada del Monte, and, being the property of the municipality, is now safe from destruction.
paintings of the Madonna and Child. On the death of his father in 1494 Raphael was left in the care of his stepmother (his own mother, Magia Ciarla, having died in 1491) and of his uncle, a priest called Bartolomeo.1

First or Perugian Period.—In what year Raphael was apprenticed to Perugino and how the interval before that was spent are matters of doubt. Vasari's statement that he was sent to Perugia during his father's lifetime is certainly a mistake. On the whole it appears most probable that he did not enter Perugino's studio till the end of 1499, as during the four or five years before that Perugino was mostly absent from his native city.2 The so-called Sketch Book of Raphael in the academy of Venice contains studies apparently from the cartoons of some of Perugino's Sistine frescoes, possibly done as practice in drawing.

This celebrated collection of thirty drawings, now framed or preserved in portfolios, bears signs of having once formed a bound book, and has been supposed to be a sketch-book filled by Raphael during his Perugian apprenticeship. Many points, however, make this tempting hypothesis very improbable; the fact that the drawings were not all originally on leaves of the same size, and the miscellaneous nature of the sketch varying much both in style and in the merit of execution—seem to show that it is a collection of studies by different hands, made and bound together by some subsequent owner, and may contain but very few drawings by Raphael himself.3

Before long Raphael appears to have been admitted to share in the execution of paintings by his master; and his touch can with more or less certainty be traced in some of Perugino's panels which were executed about 1502. Many of those who, like Crowe and Cavalcaselle, adopt the earlier date of Raphael's apprenticeship, believe that his hand is visible in the execution of the beautiful series of frescoes by Perugino in the Sala del Cambio, dated 1500; as does also M. Münz in his excellent Raphael, sa vie, Paris, 1881, in spite of his accepting the end of 1495 as the period of Raphael's first entering Perugino's studio,—a position almost impossible to reconcile. Considering that Raphael was barely seventeen when these frescoes were painted, it is hardly reasonable to attribute the finest heads to his hand; nor did he at an early age master the difficulties of fresco buono. The Resurrection of Christ in the Vatican and the Diotalevi Madonna in the Berlin Museum are the principal pictures by Perugino in parts of which the touch of Raphael appears to be visible, though any real certainty on this point is unattainable.4

About 1502 Raphael began to execute independent works; four pictures for churches at Città di Castello were probably the earliest of these, and appear to have been painted in the years 1502-4. The first is a gild-bannier painted on one side with the Trinity, and below, kneeling figures of S. Sebastian and S. Rocco; on the reverse is a Creation of Eve, very like Perugino in style, but possessing more grace and breadth of treatment. These are still in the church of S. Trinità.5 Also for Città di Castello were the coronation of S. Niccolo Tolentino, now destroyed, though studies for it exist at Oxford and Lille (Gaz. d. B. Arts, 1878, i. p. 48), and the Crucifixion, now in the Dudley collection, painted for the church of S. Domenico, and signed RAPHAEL VERNAS P. It is a panel 8 ft. 6 in. high by 5 ft. 5 in. wide, and contains noble figures of the Virgin, St John, St Jerome and St Mary Magdalene. The fourth painting executed for this town, for the church of S. Francesco, is the exquisitely beautiful and highly finished Sposalizio, now in the Brera at Milan, signed and dated RAPHAEL VERNAS MDIII. This is closely copied both in composition and detail from Perugino's painting of the same subject now at Caen, but is far superior to it in sweetness of expression and grace of attitude. The Temple of Jerusalem, a domed octagon with outer ambulatory in Perugino's picture, is reproduced with slight alterations by Raphael, and the attitudes and grouping of the figures are almost exactly the same in both. The Constable Madonna is one of Raphael's finest works, painted during his Perugian period; it is a round panel; the motive, the Virgin reading a book of hours, is a favourite one with him, as it was with his father Giovanni. This lovely picture was lost to Perugia in 1871, when Count Constable sold it to the emperor of Russia for £13,200.

Second or Florentine Period, 1504-1508.—From 1504 to 1508 Raphael's life was very stirring and active. In the first half of 1504 he visited Urbino, where he painted two small panels for Duke Guidobaldo, the St George and the St Michael of the Louvre. His first and for him momentous visit to Florence was made towards the end of 1504, when he presented himself with a warm letter of recommendation6 from his patroness Joanna della Rovere to the gonfaloniere Pier Soderini. In Florence Raphael was kindly received, and, in spite of his youth (being barely of age), was welcomed as an equal by the majority of those great artists who at that time had raised Florence to the position of first of all artist cities of the world. At the time of his arrival the whole of artistic Italy was being excited to enthusiasm by the cartoons of the battle of Anghiari and the war with Pisa, on which Leonardo da Vinci and Michelangelo were then devoting their utmost energies. To describe the various influences under which Raphael came, and the many sources, from which he drank in stores of artistic knowledge, would be to give a complete history of Florentine art in the 15th century.7 With astonishing rapidity he shook off the mannerisms of Perugino, and put one great artist after another under contribution for some special power of drawing, beauty of colour, or grace of composition in which each happened to excel. Nor was it from painters only that Raphael acquired his enlarged field of knowledge and rapidly growing powers. Sculptors like Giberti and Donatello must be numbered among those whose works helped to develop his new-born style.8 The Carmine frescoes of Masaccio and his friends, which Raphael had studied, were among the chief methods of dramatic expression.9 Among his contemporaries it was especially Signorelli and Michelangelo who taught him the importance of precision of line and the necessity of a thorough knowledge of the human form.10 From da Vinci he learnt subtleties of modelling and soft beauty of expression,11 from Fra Bartolommeo nobility of composition and skilful treatment of drapery in dignified folds.12 The friendship between Raphael and the last of these was very close and lasted for many years. The architect Baccio d'Angolo was another of his special friends, at whose house the young painter enjoyed social intercourse

1 The administration of Giovanni Santi's will occasioned many painful family disputes and even appeals to law; see Pungileoni, El. Santi della Madonna.

2 Crowe and Cavalcaselle (Life of Raphael, vol. i., London, 1882) adopt the notion that Raphael went to Perugia in 1495, but the reasons with which they support this view appear insufficient.

3 See Raphael's expert examination of the Sketch Book by Morelli, Italian Masters in German Galleries, translated by Mrs Richter (London, 1882); according to Morelli, only two drawings are by Raphael. Schmarsow, "Raphael's Skizzenbuch in Venedig, in Preussische Kabinett der Antiken," xvi, p. 106, 108 (Berlin, 1883), takes the opposite view. But Kahl, Das venezianische Skizzenbuch (Leipzig, 1882), follows Morelli's opinion, which has been generally adopted.

4 Parts of Perugino's beautiful triptych of the Madonna, with the archangel Raphael and Michael, painted for the Certosa near Pavia and now in the National Gallery of London, have been attributed to Raphael, but with little reason. Perugino's grand altar-piece at Florence of the Assumption of the Virgin shows that he was quite capable of producing figures equal in beauty and delicacy to the St Michael of the Certosa triptych. See Frizzi, L'Arte Italiana nella Gal. Nat. di Londra (Florence, 1886).

5 For an account of processionals painted by distinguished artists, see Mariotti, Lettere pittoriche Perugine, p. 76 seq.

6 This letter, which still exists, was sold in Paris in 1856, and is now in private hands.

7 See Minghetti, "I Maestri di Raffaello," in the Nuova Antologia, 1st August, 1881.

8 See his sketch of St George and the Dragon, in the Uffizi, largely taken from Donatello's pedestal relief outside Or San Michele.

9 See his cartoon of St Paul preaching at Athens (Victoria and Albert Museum).

10 See many of his life-studies, especially the one he sent to Albert Dürer, now at Vienna.

11 See the portrait of Maddalena Doni in the Pitti.

12 See the Madonna del Baldacchino in the Pitti.
with a large circle of the chief artists of Florence, and probably learned from him much that was afterwards useful in his practice as an architect.

The transition in Raphael's style from his first or Perugian to his second or Florentine manner is well shown in the large picture of the Coronation of the Virgin painted for Maddalena degli Oddi, now in the Vatican, one of the most beautiful that he ever produced, and especially remarkable for its strong religious sentiment—in this respect a great contrast to the paintings of his last or Roman manner which hang near it. The exquisite grace of the angel musicians and the beauty of the faces show signs of his short visit to Florence, while the general formality of the composition and certain details, such as the fluttering ribbons of the angels, recall peculiarities of Perugino and of Pinturicchio, with whose fine picture of the same subject hung close by it is interesting to compare it. Raphael's painting, though by far the more beautiful of the two, is yet inferior to that of Pinturicchio in the composition of the whole; an awkward horizontal line divides the upper group of the Coronation from that below, the apostles standing round the Virgin's tomb, filled with roses and lilies (Dante, Par. xxix. 73), while the older Perugian has skillfully united the two groups by a less formal arrangement of the figures. The predella of this master-piece of Raphael is also in the Vatican; some of its small paintings, especially that of the Annunciation to the Virgin, are interesting as showing his careful study of the rules of perspective. Several preparatory sketches for this picture exist: fig. 1 shows a study, now at Lille, for the two principal figures, Christ setting the crown on His mother's head (see fig. 2). It is drawn from two youths in the ordinary dress of the time, and it is interesting to compare it with his later studies from the nude, many of which are for figures which in the future picture were to be draped. It was at Florence, as Vasari says, that Raphael began serious life studies, not only from nude models but also by making careful anatomical drawings from dissected corpses and from skeletons.

His first visit to Florence lasted only a few months; in 1505 he was again in Perugia painting his first fresco, the Trinity and Saints for the Camaldoli monks of San Severo, now a mere wreck from injury and restorations. The date MDV and the signature were added later, probably in 1521. Part of this work was left incomplete by the painter, and the fresco was finished in 1521 (after his death) by his old master Perugino. It was probably earlier than this that Raphael visited Siena and assisted Pinturicchio with sketches for his Piccolomini frescoes. The Madonna of S. Antonio was also finished in 1505, but was probably begun before the Florence visit.

1 While at Florence he is said to have taught the science of perspective to his friend Fra Bartolommeo, who certainly gave his young instructor valuable lessons on composition in return.
2 The fresco of the Last Supper, dated 1505, in the refectory of S. Onofrio at Florence, is not now claimed as a work of Raphael's, in spite of a signature partly introduced by the restorer.
3 Raphael probably had no hand in the actual execution of the paintings; see Schmarsow, Raphael and Pinturicchio in Siena (Stuttgart, 1880), and Milanesi, in his edition of Vasari, iii. p. 515 seq., appendix to life of Pinturicchio.
4 This fine altar-piece, with many large figures, is now the property of the heirs of the duke of Ripalta, and is stored in the basement of the National Gallery, London.

The record of his visit to Siena exists in a sketch of the antique marble group of the Three Graces, then in the cathedral library, from which, not long afterwards, he painted the small panel of the same subject now in Lord Dudley's collection.

In 1506 Raphael was again in Urbino, where he painted for the duke another picture of St George, which was sent to England as a present to Henry VII. The bearer of this and other gifts was Guidobaldo's ambassador, the accomplished Baldassare Castiglione (q.v.), a friend of Raphael, whose noble portrait of him is in the Louvre. At the court of Duke Guidobaldo the painter's ideas appear to have been led into a more secular direction, and to this stay in Urbino probably belong the Dudley Graces, the miniature "Knight's Dream of Duty and Pleasure" in the National Gallery (London), and also the "Apollo and Marsyas," sold in 1882 by Morris Moore to the Louvre for £10,000, a most lovely little panel, painted with almost Flemish minuteness, rich in colour, and graceful in arrangement.

Towards the end of 1506 Raphael returned to Florence, and there (before 1508) produced a large number of his finest works, carefully finished, and for the most part wholly the work of his own hand. Several of these are signed and dated, but the date is frequently very doubtful, owing to his custom of using Roman numerals, introduced among the sham Arabic embroidered on the borders of dresses, so that the I's after the V are not always distinguishable from the straight lines of the ornament.

The following is a list of some of his chief paintings of this period: the Madonna del Gran Duca (Città); Madonna del Giardino, 1506 (Vienna); Holy Family with the Lamb, 1506 or 1507 (Madrid); the "Ansidei Madonna," 1506 or 1507 (National Gallery); the Borghese "Entombment," 1507; Lord Cowper's "Madonna" at Panshanger, 1508; "La bella Giardini".

4 This missal-like painting is about 7 in. square; it was bought in 1847 for 1000 guineas. The National Gallery also possesses its cartoon, in brown ink, pricked for transference.

In spite of some adverse opinions, frequently expressed with extreme virulence, the genuineness of this little gem can hardly be doubted by any one who carefully studies it without bias. Sketches for it at Venice and in the Uffizi also appear to bear the impress of Raphael's manner. See Delaborde, Études sur les B. Arts: . . . en Italie, i. p. 236; Gruyer, Raphael et l'antiquité, ii. p. 421; Eitelberger, Raphael's Apollo und Marsyas (Vienna, 1866); Batté, Le Raphael de M. Moore (Paris, 1859); and also various pamphlets on it by its former owner, Mr. Morris Moore.
Raphael Sanzio

1508 (Louvre); the “Essterhazy Madonna,” probably the same year; as well as the “Madonna del Cardellino” (Ufizzi), the “Tempi Madonna” (Munich), the “Colonna Madonna” (Berlin), the “Bridgewater Madonna” (Bridgewater House), and the “Orleans Madonna” (d Duc d’Aumale’s collection). The “Ansidei Madonna” was bought in 1884 for the National Gallery from the duke of Marlborough for £70,000, more than three times the highest price ever given for a picture. It was painted for the Ansidei family of Perugia as an alterpiece in the church of S. Fiorenzo, and is a work of the highest beauty in colour, well preserved and very large in scale. The Virgin with veiled head is seated on a throne, supporting the Infant with one hand and holding a book in the other. Below stands S. Niccolò da Tolentino, for whose altar it was painted; he holds a book and a crozier, and is clad in jewelled mitre and green cope, under which appear the alb and cassock. On the other side is the Baptist, in red mantle and camel’s-hair tunic, holding a crystal cross. The rich Jewellery in this picture is painted with Flemish-like minuteness. On the border of the Virgin’s robe is a date, formerly read 1507, and it is now believed to be 1508.

If this is the true one, the picture was probably begun a year or two before. A favourite method of grouping his Holy Families is that seen in the “Madonna del Cardellino” and the “Bella Giar- diniera,” in which the main lines form a pyramid. This arrangement is also used in the “Madonna del Giardino” and in the larger group, including St Joseph and St Elizabeth, known as the “Canigiani Holy Family,” now at Munich, one of the least graceful of all Raphael’s compositions. The “Entombment of Christ,” now in the Galleria Borghese in Rome, was painted during a visit to Perugia in 1507 for Lady Atalanta Baglioni, in memory of the death of her brave and handsome but treacherous son Grifonetto, who was killed in 1506 by his enemies the Oddi party. The many studies and preliminary sketches for this important picture which exist in various collections show that it cost Raphael an unusual amount of thought and labour in its composition, and yet it is quite one of his least successful paintings, especially in colour. It is, however, much injured by scraping and repainting, and appears not to be wholly by his hand. The “Madonna di Pescia of the Florentine period, owing much to Fra Bartolommeo, is also unsatisfactory in execution; being left unfinished by Raphael, it was completed by Ridolfio Ghirlandajo, by whom the ungraceful angels of the upper part and the canopy were wholly executed, and even designed. It was painted for the Dei family as an altar-piece for their chapel in S. Spirito, Florence. The “St Catherine” of the National Gallery was probably painted in 1507; its cartoon, pricked for transference, is in the Louvre. In colouring it much resembles parts of the Borghese “Entombment,” being quiet and grey in tone. To the Florentine period belong some of his finest portraits, and it is especially in these that da Vinci’s influence appears. The portraits of Angelo Doni and his wife Maddalena (Pitti) are vivid and carefully executed paintings, and the unknown lady with hard features (now in the Ufizzi) is a masterpiece of noble realism and conscientious finish. The Cartozian portrait, a graceful effemination of young men with long hair and tapering hands, now moved to Cracow, in 1871, is a work of this period, though worthy to rank with Raphael’s finest portraits its authenticity has been doubted. Very similar in style is the Herrenhausen portrait, once attributed to Giovanni Bellini, but an undoubted work of Raphael, in his second manner; it also represents a young man with long hair, close-shaven chin, a wide cloth hat and black dress, painted in half-length. The so-called Portrait of Raphael by himself at Hampton Court is a very beautiful work, glowing with light and colour, which may possibly be a genuine picture of about 1506. It represents a pleasant-looking youth with turned-up nose, not bearing the remotest resemblance to Raphael, except the long hair and black cap common to nearly all the portraits of this time. A fine but much-restored portrait of Raphael by himself, painted at Florence, exists in the Ufizzi; it represents him at a very early age, and was probably painted during the early part of his stay in Florence.

Third or Roman Period, 1508-1520.—In 1508 Raphael was painting several important pictures in Florence; in September of that year we find him settled in Rome, from a letter addressed in the warmest terms of affectionate admiration to Francia, to whom he sent a sketch for his “Adoration of the Shepherds,” and promised to send his own portrait in return for that which Francia had given him. Raphael was invited to Rome by his fellow-citizen (not relation, as Vasari says) Bramante, who was then occupied in the erection of the new church of St Peter, the foundation-stone of which had been laid by Julius II. on the 18th of April 1506. At this time the love of the popes for art had already attracted to Rome a number of the chief artists of Tuscany, Umbria and North Italy, among whom were Michelangelo, Signorelli, Perugino, Pinturicchio, Lorenzo Lotto, Peruzzi, Sodoma, and many others, and it was among this brilliant assembly that Raphael, almost at once, took a leading position. Thanks to Bramante’s friendly intervention, Julius II. (Della Rovere) soon became Raphael’s most zealous patron and friend, as did also the rich bankers Agostino Chigi (the Rothschild of his time) and Bindo Altoviti, whose portrait, at the age of twenty, now at Munich, is one of the most beautiful that Raphael ever produced.

A series of rooms in the Vatican, over the Appartamenti Borgia, were already decorated with frescoes by Bonfigli, and thereafter altered his scheme into the Entombment: an excess of study and elaboration partly account for the shortcomings of this picture.

Fig. 3.—Plan showing position of Raphael’s frescoes in the stanza.

Perugino, Piero della Francesca, Andrea del Castagno, Signorelli and Sodoma; but so rapidly had the taste of the time changed that Julius II. decided to sweep them all away and re-cover the

1 It is engraved at p. 53, vol. ii., of Dohme, Kunst und Künstler des Mittelalters (1879), which has many good reproductions of Raphael’s paintings and sketches.

2 See Symbolds, Sketches in Italy, the chapter on Perugia, mainly taken from the contemporary chronicle of Matarazzo.

3 These show that Raphael at first intended to paint a Deposition from the Cross, and afterwards altered his scheme into the Entombment; an excess of study and elaboration partly account for the shortcomings of this picture.

4 To judge of the authorship of a portrait from internal evidence is especially difficult, as in so many cases the strong individuality of the person represented obscures that of the painter.

5 Mancini, Pelziner-Antiquarische (Bologna, 1767), was the first to publish this letter; see also Müntz, Raphael, sa vie, etc., p. 315 (Paris, 1881). Minghetti (Nuova Antologia, 1883) throws doubt on the date of this letter.

walls with paintings in the more developed but less truly decorative style of Raphael. It was not without regret that Raphael saw the completion of this noble series of frescoes. One reason, that of the Stanza dell’ Incendio, painted by his master Perugino, he saved from obliteration; it still exists, well preserved, a most skillful piece of decorative work; and he also set his hand to copy a number of portrait-heads in the frescoes of Piero della Francesca before they were destroyed. Fig. 3 shows the positions of Raphael's frescoes in the stanza, which, both from their size and method of lighting, are very unsuited for the reception of these large pictures. The two most important rooms (A and B) are small, and have an awkward cross-light from opposite windows.8

Stanza della Segnatura (papal signature room), painted in 1509–11 (fig. 3). The first painting executed by Raphael in the stanza was the so-called Disputa, finished in 1509. It is very unlike the later ones in style, showing the beginning of transition from his Fideltà to his Roman manner. In the treatment of the figures it is very superior to the other frescoes; the figures are much smaller in scale, as was suited to the very moderate size of the room, and the whole is arranged mainly on one plane, without those strong effects of perspective which are so evident in the following frescoes. The whole is a study in draped draperies, a mosaic which suggests the occured—Bramante as the aged Archimedes, stooping over a geometrical diagram; a beautiful fair-haired youth on the left is Francesco Maria della Rovere, duke of Urbino; and on the extreme right figures of Raphael himself and Sodoma are introduced (see fig. 5, 3, 5). This completely being a new departure in art, and is in the frescoes of the Stanza dell' Incendio (see fig. 3), this interior is executed—Bramante as the aged Archimedes, stooping over a geometrical diagram; a beautiful fair-haired youth on the left is Francesco Maria della Rovere, duke of Urbino; and on the extreme right figures of Raphael himself and Sodoma are introduced (see fig. 5, 3, 5). This completely being a new departure in art, and is in the

The painting on the vault of this room is the next in date, and shows further transition towards the "Roman manner." In his treatment of the figures Raphael has, with much advantage, been partly guided by the painting of Perugino's vault in the next room (C). Though not without faults, it is a very skillful piece of decoration. The perspective is kept very so-called to the decorative vault, and their small scale adds greatly to the apparent size of the whole. A great part of the ground is gilt, marked with mosaic-like squares, a common practice with decorative painters—not intended to deceive the eye, but simply to break up the otherwise monotonous glare. The principal medallions in each cell of this quadruplicate vault are very graceful female figures, representing Theology, Science, Justice, and Poetry, smaller subjects, some almost miniature-like in scale, are ranged in the intermediate spaces, and each has some special meaning in reference to the medallion it adorns; some of these are painted in warm monochrome to suggest bas-reliefs. The fine painting of the "Flaying of Marsyas" is showing Raphael's study of antique sculpture: the figure of Marsyas is a copy of a Roman statue, of which several replicas exist. The very beautiful little picture of the "Temptation of Eve" recalls Albert Dürer's treatment of that subject, though only a fragment of which is contained existed between Raphael and Dürer: in 1515 Raphael sent to the German artist a most masterly life study of two nude male figures (now at Vienna); on it is written in Albert Dürer's beautiful hand the words: "And a record of its being a gift from Raphael. It is executed in red chalk, and was a study for two figures in the "Battle of Ostia" (see below).

On the wall opposite the Disputa is the so-called School of Athens.4

1 How fine these portrait-heads probably were may be guessed from Piero's magnificent frescoes at Arezzo, in the retrochoir of S. Francesco.8

2 See Brun, Die Composition der Wandgemäldes Raphaels im Vatican (Berlin), and Gruyer, Les fresques de Raphael au Vatican (Paris, 1859).

3 It need hardly be said that the name Disputa is a misnomer; there could be no dispute among the saints and doctors of the church about either the subject or the doctrine as the real presence: the monastic with the Host below and the figure of Christ above indicate his double presence both on earth and in heaven. Dr. Brun, Springer, and Hagen have published monographs in German on this painting.

4 See Trendelenburg, Uber Raphaels Schule von Athen (Berlin, 1843), and Richter (same title) (Heidelberg, 1882); the title "School of Athens" is comparatively modern.
army is not the most successful part of the fresco: the horses are very wooden in appearance, and the tight-fitting scale armour, put on in some impossible way without any joints, gives a very unreal and theatrical look to the picture. Part of the work is of pupils. In 1509 Raphael painted the "Delivery of St Peter from Prison" with a further political allusion (No. 9). It is very skilfully arranged to fit in the awkward space round the window, and is remarkable for an attempt, not much suited for fresco-painting, to combine and diffuse the three different qualities of light coming from the moon, the glory round the angel, and the torches of the sentinels.

For room C Raphael designed and partly painted the "Incendio del Borgo" (No. 11), a fire in the Borgo or Leonine City, which was miraculously stopped by Leo IV. appearing and making the sign of the cross over a window in the Vatican. On the background is shown the facade of the old basilica of St Peter, not yet destroyed when this fresco was painted. One group on the left, in the foreground, is remarkable for its vigour and powerful drawing; the motive comes from the burning of Troy: a fine nude figure of Anchises issues from the burning houses bearing on his back the old Anchises and leading the boy Asocias by the hand. Some of the female figures are designed with much grace and dramatic power. Many hands are in this last of the stanza frescoes on which Raphael himself worked. Others designed by him and painted by Giulio Romano, Gianfrancesco Penni, and other pupils were the "Battle of Ostia" (No. 12), a very nobly composed picture, and the "Oath of Leo III. before Charlemagne" (No. 14). The other great picture in this room (No. 13), the "Coronation of Charlemagne" (a portrait of Francis I. of France), is so very inferior in composition that it is difficult to believe that Raphael even made a sketch of it. For this, as for his other great hall fresco in the baptistery of Florence, he was paid 1000 florins, which was a large sum. The enormous fresco of the "Defeat of Maxentius" by Constantine (room D, No. 17) was painted by Giulio Romano, soon after Raphael's death, from a sketch by the latter: it is more harried and disagreeable in colour than most of Giulio Romano's early frescoes. Among the other very inferior frescoes in this great hall are two female figures (Nos. 15 and 16) representing Comitas and Justitia, painted on the wall in oil colours, very harmonious and rich in tone; they are usually, though wrongly, attributed to Raphael himself.

**Technical Methods employed in Raphael's Frescoes.**—Having made many studies, both nude and drapery, for single figures and groups, the painter made a small drawing of the whole composition, which was enlarged by his pupils with the help of numbered squares, drawn over it, to the full size required, on paper or canvas. Holes were then pricked along the outlines of the cartoon, and the design pounced through on to an undercoat of dry stucco on the wall, with pounded charcoal and a stiff brush. Over this, early in the morning, when the wall was laid, was laid about enough to serve for the day's painting; this of course obliterated the outline on the wall, and the part covered by the patch was again sketched in by (freehand, with a point on the wet stucco, so as to be able to go over it and to make sure that the whole face) and then, when the picture was to be dried, it was finished by drawing over it (now and again by the pupil) with the charcoal and the "carpaccio": a line impressed on the wet stucco was easily smoothed out, but a touch of the brush full of pigment sunk deeply into the moist stucco, and could not easily be effaced. It will thus be seen that Raphael's method was only the ordinary method in Leonardo's time on to the wall was to keep the general positions of the figures right, and was no guide as to the drawing of each separate part. Fig. 5 shows the portrait-heads of himself and Perugino (7), at the extreme right, from the School of Athens; on the left is visible an impressed sketch-line, and also part of the "fresco edge" of the patch on which this part is painted. The heads in this figure are less than one day's work. It will be seen that there is no attempt at any accuracy of drawing in the impressed lines. Raphael, especially in his later frescoes, worked with wonderful rapidity; three life-sized busts, or half a full-length figure, more than life-size, was a not unusual day's work. In some of the frescoes the edges of each day's patch of stucco can easily be traced, especially in the Incendio del Borgo (No. 11). Raphael has a strong stiffness in his subsequent work. A great deal of much use was made of tempera in the final touches, but less was used in the subsequent frescoes, owing to his increasing mastery of the difficulties of the process.

The paintings in the stanza were only a small part of Raphael's work between 1509 and 1513. To this period belong the Madonna of Foligno (Vatican), painted in 1511 for Sigismondo Coni; it is one of his most beautiful compositions, full of the utmost grace and sweetness of expression, and appears to be wholly the work of his hand. It has suffered much from repainting. Of about the same date are the gem-like Garvagh Madonna (National Gallery, bought for £2000; once in the possession of the Aldobrandini family), the Diadem of Virgin Mary (Louvre), and the Madonna del Pesce at Madrid. The last is a very noble picture but the design is more pleasing than the colour, which, like other paintings of Raphael's at Madrid, suggests the inferior touch of a pupil; it was executed in 1513 for S. Domenico in Naples. In addition to other easel pictures a number of his finest portraits belong to this period—that of Julius II. (Uffizi)2 of which a good replica or contemporary copy exists in the National Gallery, the so-called Fornarina in the Palazzo Barberini, the Baldassare Castiglione of the Louvre, and the unfinished portrait of Federigo Gonzaga of Mantua.

When Giovanni de' Medici, at the age of thirty-eight, became pope as Leo X., a period of the most glowing splendour and reckless magnificence succeeded the stern rule of Julius II. Agostino Chigi, the Sienei financier, was the chief of those whose lavish expenditure contributed to enrich Rome with countless works of art. For him Raphael painted, in 1513-14, the very beautiful fresco of the Triumph of Galatea in his new palace by the Tiber bank, the Villa Farnesina, and also made a large series of magnificent designs from Apuleius's romance of Cupid and Psyche, which were carried out by a number of his pupils. These cover the vault and lunettes of a large loggia (now closed in for protection); in colouring they are mostly harsh and gaudy, as is usually the case with the works of his pupils, a great contrast to the fresco of the Galatea, the greater part of which is certainly the master's own work. For the same patron he painted (also in 1513) his celebrated Sibyls of the Louvre, and the Madonna del Pesce at Madrid. The last is a very noble picture but the design is more pleasing than the colour, which, like other paintings of Raphael's at Madrid, suggests the inferior touch of a pupil; it was executed in 1513 for S. Domenico in Naples. In addition to other easel pictures a number of his finest portraits belong to this period—that of Julius II. (Uffizi)2 of which a good replica or contemporary copy exists in the National Gallery, the so-called Fornarina in the Palazzo Barberini, the Baldassare Castiglione of the Louvre, and the unfinished portrait of Federigo Gonzaga of Mantua.

1 See Montagnani, *Sala di Costantino* (Rome, 1834). Though he was never a good colourist, the great frescoes by Giulio Romano in the Palazzo del Té, Mantua, show some improvement as compared with his Roman work.
2 These three stages were usually distinguished as study, sketch and cartoon.

**Fig. 5.—Heads of Raphael and Perugino (7), from the School of Athens, showing incised lines and "fresco edges."**
in S. Maria della Pace,—figures of exquisite grace, arranged with perfect skill in an awkward space. It is not without reason that Vasari gives these the highest position among his fresco-paintings. Agostino Chigi also employed Raphael to build for him a private chapel in S. Maria del Popolo, and to make a series of cartoons to be executed in mosaic on the inner dome. The central medallion has a figure of God among clouds and angel boys, such as Raphael drew with unrivalled strength (fig. 6), and around are the eight planets, each with its pagan deity and directing angel. He has not hampered himself by any of the usual rules which should apply to the designing of mosaic; they are simply treated as pictures, with almost deceptive effects of perspective. The execution of these brilliant mosaics was carried out by the Venetian Luigi della Pace, whose signature is introduced on the torch of Cupid in the panel representing the star Venus (Ludovico della Pace Veneziano fece, 1516). These mosaics are still as perfect and brilliant as if they were the work of yesterday. Probably in the early years of Leo X.'s reign were painted the Madonna della Seggiola (Pitti), the S. Cecilia at Bologna (not completed till 1516), the miniature Vision of Ezekiel (Pitti) and three important pictures at Madrid. The latest of these, known as Lo Spasimo, from the church at Palermo, for which it was painted, is one of Raphael's finest compositions, representing Christ bearing His Cross. It bears signs of Giulio Romano's hand in its heavy colouring with unpleasant purple tones. The Madonna called Della Pesca has much changed from the fresco to the cartoons; in design it recalls Leonardo da Vinci. The small Madonna della Rosa is the most perfect in colour of all the master's pictures in the Madrid Gallery, and is usually rather undervalued; it is a most graceful little picture. The portrait of Leo X. with Cardinals de' Rossi and de' Medici, in the Pitti, is one of his finest portrait-pictures, especially as regards the figure of the pope. Little is known about the Madonna di S. Sisto, the glory of the Dresden Gallery; no studies or sketches for it exist. In style it much resembles the Madonna di Foligno; it is less injured by restoration than the latter.

Among the latest works of Raphael are the large "St Michael and the Devil," in the Louvre, signed "Raphael Urbinas pingebat, MDXVIII.," and the very beautiful portrait of the Violin-player, in the Sciarra-Colonna Palace in Rome, also dated 1518; this last bears much resemblance to the painter himself. The British Museum possesses one of Raphael's finest portraits, though only a chalk drawing, that of his friend the painter Timoteo della Vite, a master-piece of expression and vigour; it is executed in black and red, and is but little inferior in chromatic effect to an oil-painting; it is life size, and is executed with wonderful skill and evident keen interest in the subject.

The tapestry cartoons, seven of which are in the Victoria and Albert Museum, were painted by pupils from Raphael's designs. They are part of a set of ten, with scenes from the Acts of the Apostles, intended, when copied in tapestry, to adorn the lower part of the walls of the Sistine chapel. The tapestries themselves, worked at Brussels, are now, after many vicissitudes, hung in a gallery in the Vatican; the set is complete, thus preserving the design of the three lost cartoons. The existing seven, after being cut up into strips for use on the looms, were bought by Rubens for Charles I. The tapestry copies are executed with wonderful skill, in spite of Raphael's having treated the subjects in a purely pictorial way, with little regard to the exigencies of textile work. The designs are reversed, and the colours far more brilliant than those of the cartoons, much gold and silver being introduced. The noble figure of Christ in the Delivery of the Keys to St Peter is especially treated with much magnificence by the addition of a number of large gold stars all over the drapery, which spoil the simple dignity of the folds. The rich framework round each picture, designed by Raphael's pupils, probably by Penni and Giovanni da Udine, exists in the tapestries and adds greatly to their decorative effect. The cartoons were executed in 1515 and 1516, and the finished tapestries were first exhibited in their place in the Sistine chapel on the 26th of December 1519—a very short time for the weaving of such large and elaborate pictures. The three of which the cartoons are lost represent the Martyrdom of St Stephen, the Conversion of St Paul, and St Paul in Prison at Philippi. Probably no pictures are better known to have been more often engraved and copied than these seven cartoons.

The Transfiguration.—In 1519 Cardinal Giuliano de' Medici (afterwards Clement VII), as bishop of Narbonne, ordered two altar-pieces for his cathedral—the one by Raphael, the other by Raphael's Venetian rival Sebastiano del Piombo. That by the latter painter is the noble Resurrection of Lazarus, now in the National Gallery, in the drawing of which the Venetian received important aid from Michelangelo. Several cartoons for Raphael's work show that he first intended to paint a Resurrection of Christ as a pendant to Sebastiano's subject, but soon altered his scheme into the Transfiguration. The eight or nine existing studies are scattered through the Oxford, Lille, Windsor and some private collections. A great part of the lower group was unfinished at the time of the painter's sudden death in 1520, and a good deal of the heavy colouring of Giulio Romano is visible in it. On the death of Raphael the picture became too precious to send out of Rome, and Cardinal de' Medici contented himself with sending the Resurrection of Lazarus to Narbonne. The Transfiguration was bequeathed by him to the monks of S. Pietro in Montorio, in whose church it remained till it was stolen by Napoleon I. It now hangs in the Vatican Gallery.

Architectural Work.—Though he designed but few buildings, Raphael's great repute even in this branch of art is shown by the facts that the mausoleum of Pope Julius II, now in the Roman Church of Ss. Nereo and Achilleo, was designed by Raphael, and that when the new Saint Peter's was begun in 1506, the Pope entrusted the direction of the work to him. He designed it as a basilica with two aisles.（由于原稿较长，此处仅展示部分）
fact that Bramante, before his death in March 1514, specially requested that Raphael should be made his successor as chief architect of St Peter's. To this most important post he was appointed by a brief of Leo X, dated the 1st of August 1514. The programme for him was given by the development mark on its design. Another work of Bramante's, completed by Raphael, was the graceful Cortile di S. Damaso in the Vatican, including the loggia, which were decorated with stucco-reliefs and paintings under his own supervision, pupils, but only very partially from his designs. The Palazzo dell'Aquila, built for Giovanni Battista Brancaio, and destroyed in the 17th century during the extension of St Peter's, was one of Raphael's chief works as an architect. He also designed the little cross of St Peter's, interred in the choir, known as S. Eligio degli Orefici, which still exists near the Tiber, almost opposite the Farnesina gardens, a work of but little merit. According to M. Geymüller, whose valuable work, Raffaelo come Architetto (Milan, 1858), incidentally supposed by Raphael, the fact of Architetto Aquila, afterwards inclined to Raphael, was, as well as its palace-like stables, designed by Raphael; but internal evidence makes this very difficult to believe. It is a noted character of the 15th century for Raphael, whose taste seems to have been strongly inclined to the more developed classic style, of which Palladio afterwards became the chief exponent. The Palazzo Vldoni, near S. Giovanni in Laterano, is usually attributed to Raphael, but an original sketch for this in Peruzzi's own hand has recently been identified among the collection of drawings at Siena; this, however, is not a certain proof that the design was not Raphael's. M. Geymüller assigns the openings of the Villa Madama, on the slope of Monte Mario, above Rome, really designed by him, though its actual carrying out, and the unrivalled stucco-reliefs which make its interior one of the most magnificent palaces in the world, are due to Giulio Romano and Giovanni da Udine, as men of the 15th century. The original design for this villa made by Raphael himself has been discovered by M. Geymüller. Another architectural work was the little Chigi chapel in S. Maria del Popolo, built in 1516, for the dome of which the above-mentioned mosaics were designed (see fig. 3). One of his pupils, who is supposed by M. Geymüller to have died of his death he was preparing to build himself a handsome palace near the church of S. Eligio; the deed for the purchase of its site was signed by him only a few days before his last short illness. Though not completed till 1530, the Palazzo Pandolfini at Florence was also designed by him; it is a dulle scholastic building without any special beauty either in proportion or treatment of the mass; it is illustrated by Montigny and Famin, Architectura Toscana (Paris, 1851).

A sober criticism of Raphael's architectural works must force one to refuse him a high position in this branch of art. In the church of S. Eligio and the Chigi chapel he is merely a copyist of Bramante, his province as an architect by no means invention or even mastery of the first principles of architectural design. His details are, however, often delicate and refined (especially in the Palazzo Pandolfini), and he was supremely successful in the decorative treatment of richly ornamented interiors when he designed them as the Vatican snare, sacrifice the room to the frescoes on its walls.

Sculpture.—That Vasari is right in attributing to him the model for the beautiful statue of Jonath in the Chigi chapel (fig. 7) is borne witness to by two important documents, which show that his almost universal talents led him to attempt with success the preliminary part of the sculptor's art, though there is no evidence to show that he ever worked on marble. One of these is a letter written to Michelangelo to warn him that Raphael had been in too much of these delicate and figurative time are free from the too pictorial character which is an obvious fault in the very magnificent reliefs of the Villa Madama.

1 See Mariani, La Bibbia nelle Loggie del Vaticano (Rome); Anon., Disegni di Sculture e Decorazioni (London, 1854), pls. 1-5. Too great a share in the decoration of the loggie is usually given to Raphael; not only the harsh colour but also the feebledness of much of the drawing shows that he could have had but little to do with it. See also Briscoe's Drawings, &c. (London, 1854), pls. 6-12, and Raffaele Santi, Ornati della Villa Madama, &c. (Rome, 1875).

2 Two other little known but very beautiful architectural works, executed under Raphael's influence by his pupils, are the bathroom of Chief Michelangelo della Valtolina in the church of St. Eligio, and the tiles in the castle of S. Angelo, both richly decorated with delicate stucco-reliefs and paintings, treated after a classical model.

4 Compare this latter subject on reverses of the beautiful drachms of Tarentum, c. 300 B.C.

5 The very beautiful and elaborate choir-stalls of the church of S. Pie in Conregio, with panels carved in relief, executed in 1535 by Stefano da Bergamo, are mainly adapted from Raphael's designs.

6 Campori, Notizie stor. d. Matiola di Ferrara (3rd ed., Pesaro, 1878), p. 189, Fig. 7. — Statue of Jonath in the Chigi chapel, designed by Raphael, sculptured by Lorenzetto; heroic size.

7 See Appendix, p. 446, vol. iv., of Milanesi's edition of Vasari; Remondi, Dei pittori, &c. of Raffaello (Florence, 1872); Gennarelli, Sopra una Scultura di Raffaello (Florence, 1873). The evidence which would attribute this piece of sculpture to Raphael is almost worthless. See on the S. Peter's group, Gudé, Annales de l'École des Chartes, vol. iv. (Paris, 1872).

8 Compare this latter subject on reverses of the beautiful drachms of Tarentum, c. 300 B.C.

9 The very beautiful and elaborate choir-stalls of the church of S. Pie in Conregio, with panels carved in relief, executed in 1535 by Stefano da Bergamo, are mainly adapted from Raphael's designs.

The evidence which would attribute this piece of sculpture to Raphael is almost worthless. See on the S. Peter's group, Gudé, Annales de l'École des Chartes, vol. iv. (Paris, 1872).
important alterations made in the execution of the picture. Raimondi's engraving of the S. Cecilia of Bologna in design is very inferior to that of the actual painting. Several of Raphael's most important compositions are known to us only by these early engravings, e.g., the Masacre de los Innocentes (engraved by Raimondi), which is one of his finest works, both for skillful composition and for masterly drawing of the nude. Another magnificent design is the Judgment of Paris, containing a large number of figures; and this work is studied by scholars of both art and beauty. A standing figure of Lucretia¹ about to stab herself is also one of his most lovely figures. Many of Raphael's studies for Marcantonio's engravings still exist.

Archaeology.—As an antiquary Raphael deserves to take the highest rank. His report to Leo X, in 1518 is an eloquent plea for the preservation of ancient buildings. In 1515 he had been appointed by Leo X, inspector of all excavations in Rome and within the see of St. John Lateran. His trustworthy accuracy of judgment, and the directness of his methods of decoration, is clearly shown in many of his frescoes, and especially in the graceful stucco reliefs and painted groteschi, of which he and his pupils made such skillful use in the decorations of the Vatican loggie, the Villa Madama and elsewhere.²

Raphael's Fame.—Among all the painters of the world none has been so universally popular as Raphael, or has so steadily maintained his pre-eminent reputation throughout the many changes in taste which have taken place in the last three and a half centuries. Apart from his combined merits as a draughtsman, colourist and master of graceful composition, he owes the constancy of admiration which has been felt for him partly to the wide range of his subjects, but still more to the wonderful variety of his style. If the authorship of his paintings were unknown, who would guess that the Sposalizio of the Brera, the Madonna del Baldacchino of the Pitti, and the Transfiguration could possibly be the work of one painter? In the seventeenth or eighteen years which composed his short working life he passed through stages of development for which a century would not have seemed too long, while other painters lived through the same changeful time with but little alteration in their manner of work. Perugino, who outlived his wonderful pupil, completed in 1521 Raphael's San Severo fresco in a style differing but little from his paintings executed in the previous century.

Versatility of power Raphael (as a painter) remains almost without a rival; whether painting an altar-piece for a church, a large historical fresco, a portrait or decorative scenes from classical mythology, he seems to excel equally in each; and the widely differing methods of painting in tempera, oil or fresco are employed by him with apparently equal facility. His range of scale is no less remarkable, varying from a miniature, finished like an illuminated MS., to colossal figures in fresco dashed in with inimitable breadth and vigour.

His personal beauty, charm of manner and deep kindness of heart endeared him to all who knew him.³ His sincere modesty was not diminished by his admission as an equal by the princes of the church, the distinguished scholars and the world-famed men of every class who formed the courts of Julius II. and Leo X. 'In accordance with the spirit of the age he lived with considerable display and luxury, and was approached with the utmost deference by the ambassadors of foreign princes, whether their master desired a picture or, as the duke of Ferrara said of Raphael, his works were bought for gold and silver. To his pupils he was as a father, and they were all, as Vasari says, "vinti dalla sua cortesia"; they formed round him a sort of royal retinue, numbering about fifty youths, each talented in some branch of the arts.⁴ Giulio Romano and Gianfrancesco Penni, his two favourite pupils, lived with him in the Palazzo of Bramante, a house near St. Peter's, where he resided during the greater part of his life in Rome. This fine

¹See a pedestal is inscribed in Greek—"Better to die than live basely." ²Published by Visconti, Lettera di Raffaello a Leone X. (Rome, 1840); see also Müntz, "Raphael Archéologue," &c., Gaz. des B. A., 1840. ³See Gruner, Raphael et l'Antiquité (Paris, 1864). ⁴See the eloquent eulogy of his character at the end of Vasari's Life.
RAPIER. The name given to two distinct types of sword. Originally the "rapier" (Fr. rapière) was a long, two-edged and pointy, jereau, often with a wide cup, held with the dagger in fencing and duelling chiefly as a thrusting weapon, the dagger taking a secondary position. This was the typical duelling sword of the 16th and 17th centuries. In the 18th century the "small sword" took its place; this was a pointed weapon only, the "cut" having entirely dropped out, and the dagger being discarded. The word rapier is of doubtful origin. Du Cange (Glossarium, s.v. "Rapparia") quotes an example of the word used as an adjective to qualify espée as early as 1474, and gives as a conjectural derivation Gr. ραπιέων=Lat. caedere, to cut. Skeat (Etym.Dict., 1910) follows the suggestion of Diez that rapière is from raspière, a rasp or poker, and was a name given in contempt by the old cut-and-thrust fencers to the new weapon. Spanish has raspadora, a raker, and there are several 16th and 17th century quotations alluding to the contempt with which the rapier was greeted, and to its Spanish origin (see FENCING and SWORD).

RAPIN, Paul de (1661-1723), sieur of Thoyras, French historian, was the son of Jacques de Rapin, avocat at Castres (Tarz), where he was born on the 25th of March 1661. He was educated at the Protestant academy of Saumur, and in 1679 became an advocate, but soon afterwards entered the army. The revocation of the Edict of Nantes in 1685, and the death of his father led him to come to England; but, unable to find employment there, he crossed to Holland and enlisted in the company of French volunteers at Utrecht commanded by Daniel de Rapin, his cousin-german. He accompanied the prince of Orange to England in 1688, and during the Irish campaign he took part in the siege of Carrickfergus and the battle of the Boyne, and was wounded at the battle of Limerick. Soon afterwards he was promoted captain; but in 1693 he resigned in order to become tutor to the earl of Portland's son. After travelling with his charge, he settled with his family in Holland, first at the Hague, then, for economy's sake, at Wesel, in 1707, where he began his great work, L'Histoire d'Angleterre. Though he was of a strong constitution, the seventeen years' application ruined his health. He died in 1725.

Rapin was also the author of a Dissertation sur les Whigs et les Tories (1717). L'Histoire d'Angleterre, embracing the period from the invasion of the Romans to the death of Charles I., was printed at the Hague in 1724 in 8 vols. It was translated into English and published in England by Tindal in 2 vols. folio, 1729-31. Rapin's history of England was almost the only one available in France in the first 18th century.

RAPPORT, Samuel Judah Löb (1790-1886), Jewish scholar, was born at Lemberg in 1790. After various experiences in business, Rapport became successively rabbi of Tarnopol (1837) and of Prague (1840). He was one of the founders of the new learning in Judaism. His chief work was the first part of an (unfinished) encyclopedia (Erekh Milliu, 1832). Equally notable were his biographies of the Gaon Saadiah, Nathan author of the Arakh, the Gaon Hai, Eleazar Kalir and others. He died at Prague in 1867.

RAPARRÉ, properly a short pike (Irish raparo); the term being hence applied in the war in Ireland from 1688-90. The word was first used by Dr. Richard Pococke. It thus became synonymous with robber or freebooter, and in 1797 appears in the title of an act (6 Anne, cap. 11) "for the more effectual suppression of . . . robbers and raparees.

RAPPOLOTSWEILER (French Ribeauville), a town of Germany, in the imperial province of Alsace-Lorraine. Pop. (1905) 5086. It lies at the entrance of the valley of the Strengbach, under the eastern slope of the Vosges mountains, 33 m. S.W. of Strassburg on the railway to Basel, being connected with its station on that line, 2½ m. distant, by a tramway. It is in part surrounded by ancient walls, and has many picturesque medieval houses, and two old churches, of St Gregory and St Augustine, both fine Gothic buildings. The town hall contains a valuable collection of antiquities. The Carolabad, a saline spring with a temperature of 64° F., which had a great repute in the middle ages, was rediscovered in 1888, and made Rappoltsweiler a watering-place. The industries include the spinning and weaving of cotton and wool, printing, dyeing and tanning, while there is a brisk trade in wine.

Rappoltsweiler, known in the 8th century as Rathaldovila, passed from the bishops of Basel to the lords of Rappoltstein, who were among the most famous nobles in Alsace. The lord of Rappoltstein was the king or protector of the wandering minstrels of the land, who purchased his protection by paying him a tax. When the family became extinct in 1673 this office of king of the pipers (Pfeiferkönig) passed to the counts palatine of Zweibrücken-Birkenfeld. The minstrels had a pilgrimage chapel near Rappoltsweiler, dedicated to their patron saint, Maria von Dunsebach, and here they held an annual feast on the 8th of September. Near the town are the ruins of three famous castles, Ulrichsburg, Girsberg and Hohrappoltstein, which formerly belonged to the lords of Rappoltstein.

See Bornhard, Recherches sur l'histoire de la ville de Rappoltsweiler (Colmar, 1888); and Kube, Rappoltsweiler, das Carolabad und Umgebung (Strassburg, 1905). For the lords of Rappoltstein, see Brieger, Die Herrschaft Rappoltsweiler (Strassburg, 1907).

RARE EARTHS, in chemistry, the name given to a group of oxides of certain metals which occur in close association in some very rare minerals. Although these metals resemble each other in their chemical relationships, it is convenient to subdivide them into three groups: the cerium, terbium and ytterbium groups. The first includes scandium (Sc, 44-1), yttrium (Y, 89-0), lanthanum (La, 139-0), cerium (Ce, 140-25), praseodymium (Pr, 140-6), neodymium (Nd, 144-3), and samarium (Sa, 150-4); the second includes europium (Eu, 152-0), gadolinium (Gd, 157-3), and terbium (Tb, 150-2); and the third includes dysprosium (Dy, 162-5), holmium (Ho, 67-3) erbium (Er, 167-4), thulium (Tm, 168-5), ytterbium or neodyttium (Yb, 172-0), and lutecium (Lu, 174-0); the letters and numbers in the brackets are the symbols and atomic weights (international). Although very rare, a large number of minerals contain these metals; they are chiefly found in Scandinavia, parts of the Ural, America and Australia, generally associated in pegmatites and eruptive rocks, and more rarely in sedimentary deposits. They are usually silicates, but many complex tansaltles, niobates, phosphates, uranates and fluorides occur. The chief mineral species are monazite, a phosphate of the cerium metals, containing thorium (this mineral supplies the ceria and thorium employed in making incandescent gas mantles); cerite, a hydrated silicate of calcium and the cerium metals; gadolinite, a silicate of beryllium, iron, and the yttrium metals; samarskite, a niobate and tantalate of both the cerium and yttrium metals, with uranium, iron, calcium, etc.; and kileluhatite, a titanosilicate of yttrium, iron, calcium and aluminium; other species are fergusonite, orthite, aeschynite, euxenite and thorite.

The chemistry of this group may be regarded as beginning with Cronstedt's description of the mineral cerite from Bastnaes in 1755, and the incorrect analyses published by T. O. Bergman and Don Fausto de Elhuyar in 1784. Ten years later Gadolin, the first to isolate the metallic elements gadolinium and yttrium, confirmed Cronstedt's analysis. Both of these discoveries were made almost independently by Gadolin, who named the new element gadolinium in his honor, having been the Rappoltsweiler, C. H. Rappoltsweiler, a town of Germany, in the imperial province of Alsace-Lorraine. Pop. (1905) 5086. It lies at the entrance of the valley of the Strengbach, under the eastern slope of the Vosges mountains, 33 m. S.W. of Strassburg on the railway to Basel, being connected with its station on that line, 2½ m. distant, by a tramway. It is in part surrounded by ancient walls, and has many picturesque medieval houses, and two old churches, of St Gregory and St Augustine, both fine Gothic buildings. The town hall contains a valuable collection of antiquities. The Carolabad, a saline spring with a temperature of 64° F., which had a great repute in the middle ages, was rediscovered in 1888, and made Rappoltsweiler a
yttria into two new bases which he called "erbia" and "terbia," and a true yttria, but in 1850 N. J. Berlin denied the existence of Mosander's "erbia," and gave this name to his "terbia." The new erbium has itself proved to be a mixture. Marignac in 1878 separated an ytterbia which was split by Nilson in 1875 into scandia (the metal of which proved to be identical with Mendeleeff's predicted eka-boron) and a new ytterbia, which, in turn, was separated by Urbain in 1907 into neodyttetia and lutecia (C. A. von Welsbach proposed for these elements the names aldebarium and cassiopeium). Berlin's erbium was also examined by Soret in 1878 and by Cleve in 1879; the new base then isolated, Soret's X or Cleve's holmia, was split by Lecoq de Boisbaudran in 1886 into a true holmia and a new oxide dysprosia. The same erbium also yielded another base, thulia, to Cleve, in 1879, in addition to true erbium. The original erbium of Mosander was confirmed by M. A. Delafontaine in 1878 and renamed terbia; this base was split by Marignac in 1886 into gadolinia and true terbia. These relations are schematically shown below; the true earths are in italics, mixtures in Roman.

Methods of Separation.—The small proportions in which the rare earths occur in the mineral kingdom and the general inter-mixture of several of them renders their efficient separation a matter of much difficulty, which is increased by their striking chemical resemblances. While it is impossible to treat the separations in detail, a general indication of the procedure may be given. The first step is to separate the rare earths from the other components of the material. For this purpose the mineral is evaporated with sulphuric or hydrochloric acid, or fused with potassium bisulphate, and the residue extracted with water. The solution of chlorides or sulphates thus obtained is treated with sulphuric acid, to remove copper, bismuth and molybdenum, and the filtrate, after the ferrous iron has been oxidized with chlorine, is precipitated with oxalic acid. The oxalates (and also thorium oxalate) may be converted into oxides by direct heating, into nitrates by dissolving in nitric acid, or into hydroxides by boiling with potash solution. The thorium may be removed by treating the nitrate solution with hydrogen peroxide, and warming, whereupon it separates as thorium peroxide. The next step consists in neutralizing the nitric acid solution and then saturating with potassium sulphate. Double salts of the general formula $R_2(SO_4)_3$. $3K_2SO_4$ are formed, of which those of the cerium group are practically insoluble, of the terbium group soluble, and of the ytterbium group very soluble. The sulphates thus obtained may be converted into oxalates or oxides and the saturation with potassium sulphate repeated.

To separate the individual metals many different methods have been proposed; these, however, depend on two principles, one, on the different basicities of the metals, the other, on the different solubilities of their salts. Bahr and Bunsen worked out a process of the first type, which utilized the fractional decomposition of the nitrates into oxides on heating. The mixture is decomposed into nitrates, which are then mixed with an alkali nitrate to lower the melting-point, and the mixture fused. The nitrates decompose in order of the basicities of the metals, and after a short fusion the residue is extracted with boiling water, and the basic salt which separates when the solution is cooled is filtered off. This contains the most negative metal; and the filtrate, after evaporation and a repetition of the fusion and extraction, may be caused to yield the other oxides. A second method, based on the same principle, consists in the fractional precipitation by some base, such as ammonia, soda, potash, aniline, &c. The neutral nitrates are dissolved in water, and the base added in such a quantity to precipitate the oxides only partially and very slowly. Obviously the first deposit contains the least basic oxide, which by re-solution as nitrate and re-precipitation yields a purer product. To the filtrate from the first precipitate more of the base is added, and the second less basic oxide is thrown down. By repeating the process all the bases can be obtained more or less pure.

Many processes depending upon the different solubilities of certain salts have been devised. They consist in forming the desired salt and fractionally crystallizing. The mother liquor is concentrated and the crystals obtained by filtering the crystals being added to the filtrate to re-crystallization of the first deposit. These operations are repeated after the manner shown in the following scheme; the letter C denotes crystals, the M.L mother liquor, whilst a bracket means mixing before re-crystallization.

```

| Original Solution |
|-------------------|----------------|
|                   | C             |
|                   | C             |
|                   | C             |
|                   | C             |
|                   | C             |

|                   | C             |
|                   | C             |
|                   | C             |
```

Obviously the fractions contain salts which increase in solubility as one passes from the left to right, and with sufficient care and patience this method permits a complete separation. The salts which have been used include the sulphates, nitrates, chromates, formates, oxalates and malonates. R. J. Nilson (Ann. chim. anal. chem., 1904, 41, p. 97) separates the cerium earths by forming the double potassium carbonates, e.g., $K_2CO_3(C_2O_4)_3$, $12H_2O$, which are soluble in potassium carbonate solution, being precipitated by cerium carbonate, potassium sulfate, and neodymium on diluting the solution; C. A. von Welsbach (Chem. Neues, 1907, 95, p. 196; 1908, 98, pp. 223, 297) separates the metals of the ytterbium group by converting the basic nitrates into double ammonium oxalates and fractionating; C. James (Biol., 1907, 95, p. 181; 1908, 97, pp. 215, 285) formed the oxalates of the ytterbium earths and dissolved them in dilute ammonia saturated with ammonium carbonate; by boiling this solution the earths are precipitated in the order yttrium, holmium, and dysprosium, and erbia; he also fractionally crystallized the borates (see, e.g., Jour. Amer. Chem. Soc., 1910, 32, p. 517, for thorium). Complex organic reagents are also employed. Neish (Jour. Amer. Chem. Soc., 1904, 26, p. 780) used meta-nitrobenzoic acid; O. Holmberg separates neodymum and praseodymum, and thorium and lanthain and samaria by precipitating with meta-nitrobenzene sulphonic acid, and has investigated many other organic salts (see Abs. J. C. S., 1907, ii. p. 90), whilst H. Erdmann and F. Wirth (Ann., 1908, 361, p. 180) employ the 1-8 normal sulphate.

In order to determine whether any such method for separating these earths is really effective, it is necessary to analyse the fractions. For this purpose two processes are available. We may precipitate the oxide from the filtrate by adding a quantity of the base, and the filtrate is obtained by heating. A weighed quantity of the oxide is now taken and converted into sulphate by evaporating with dilute sulphuric acid. The sulphate is gently dried until the weight is constant, and from this weight the equivalent of the earth can be calculated. When repeated fractionation is attended by no change in the equivalent we may conclude that only one element is present. This process, however, is only rough, for the elements with which we are dealing have very close equivalents. A more exact method employs the
spectra—spark, arc, phosphorescence and absorption; the evidence, however, cannot in all cases be accepted as conclusive, but when taken in conjunction with chemical tests it is the most valuable method.

**Chemical Relations.**—The rare earth metals were at first regarded as divalent, but determinations of the specific heats of cerium by Mendéélev and Hillebrand and of lanthanum and didymum by Hillebrand pointed to their tervalency; and this view now has general acceptance. They are comparatively reactive; they burn in air to form oxides of the type Me₂O₃; combine directly with hydrogen at 200°–300° to form hydrides of the formula MH₄ or MH₃; nitrates of the formula MN₄ are formed by passing nitrogen over the oxides mixed with magnesium; whilst carbides of the type MC₂ are obtained in the electrolytic reduction of the oxides with carbon. In addition to the oxides Me₂O₃, several, e.g. cerium, terbium and neodymium, form oxides of the formula MO₃. The sesquioxides are bases which form salts and increase in basicity in the order Sc, Yb, Tm, Er, Ho, Tb, Gd, Sm, Y, Ce, Nd, Pr, La; the latter hissing with water like quicklime.

The placing of these elements in the periodic table has attracted much attention on account of the many difficulties which it presented. The simplest plan of regarding them all as trivalent and placing them in the third group is met by the fact that there is not room for them. Another scheme scatters them in the order that their atomic weights in the last four groups of the system, but groups of objections have been urged against this plan. A third device places them in one group as a bridge between barium and tantalum. This was suggested by Benedick in 1903 (Zeit. anorg. Chem., 1904, 30, p. 41), and adopted in Werner's table of 1905 (Ber. 38, p. 914), whilst in 1902 Brauner (ibid. 32, p. 18) placed the group as a bridge on a plane perpendicular to the planes containing the other elements, thus expanding the table into a three-dimensional figure. The question has also been considered by Sir William Crookes (Journ. Chem. Soc., 1888, 53, p. 487; 1889, 55, pp. 257 et seq.), whose inquiries led him to a new conception of the chemical elements.

Schilling, Das Vorkommen der seltenen Erden im Mineralreich (1904).

**RAS.** The Arabic for a "head," hence a cape, promontory or headland; a common word in place names.

**RASCHMIDT** (1855-1912), Jewish scholar, wrote extensively on the inferences of a rabbinate, especially descriptive of camp-followers or the dregs of an army, or of the lowest of the people; now only of a single person, in the sense of a rogue or knave. The origin of O.Fr. rascelle, modern rascelle, from the word came into English, is uncertain. The word was early used, in hunting, for the weaker or poorer male deer of a herd; the word has been connected with O.Fr. rascelle, which is not true, rasper, to scrape, rake, in the sense of the off-scourings of the herd.

**RASHBA** (1085-1174), Jewish scholar, so called from the initials of his full name, Rabbi Samuel ben Meir, was a leading member of the French school of Biblical exegesis. He was a grandson of Rashi (q.v.), but differed in his method of interpretation. He wrote commentaries on the Pentateuch and other parts of the Scriptures. Rashba adopts a natural interpretation, and a rational view of the traditions (as opposed to the homiletical and traditional) method; thus in agreement with the modern school) Rashba (on Gen. i. 5) maintained that the day began at dawn and not from the previous sunset (as later Jewish custom assumed). Another famous interpretation was Rashba's view that the much disputed phrase in Gen. xlix. 10 must be rendered "Until he cometh to Shiloh," and refers to the division of the kingdom of Judah after Solomon's death. Rashba's notes on the Bible are remarkable for brevity, but when he comments on the Talmud—he wrote explanations on several tracts—he is equally noted for proximity.

**RASHI** (1040-1105), Jewish scholar. Rabbi Solomon Izakoff (son of Isaac), usually cited as Rashi from the initials of those words, was born at Troyes in 1040 and died in the same town in 1105. Legends concerning him are many. Isaac's wife, shortly before the birth of their famous son, was walking one day down a narrow street in Worms, when two vehicles moving in opposite directions seemed about to crush her. As she went hopelessly against a wall, it miraculously fell inwards to make a niche for her. So with his education. Legend sends the student to southern France, and even on a tour of the world. At an inn in the Orient he cured a sick monk, who later on, as bishop of Olmütz, returned the kindness by saving the Jews from massacre. In fact, Rashi never went farther than from the Seine to the Rhine; the utmost limit of his travels were the academies of Lorraine. Situated between France and Germany, Lorraine was more French than German, and French was the common language of Jew and Christian. This is shown by the glosses in Rashi's works, almost invariably in French. He seems to have passed the decade beginning with 1055 in Worms, where the niche referred to above is still shown. Within this, it is said, Rashi was wont to teach. A small edifice on the east of the synagogue is called the "Rashi Chapel," and the "Rashi Chair," raised on three steps in the niche, is one of the objects of the pious admiration of pilgrims. At Worms Rashi worked under Jacob ben Yaqar, and at Mainz under Isaac ben Judah, perhaps combining at the same time the functions of teacher and student. Besides the oral tuition that he received, the medieval schools habitually kept the notes of former teachers. From these Rashi learn much, and probably he incorporated some of these notes in his own works. In the middle ages there was a communism in learning, but if Rashi used some of the stones quarried and drafted by others, it was to his genius that the finished edifice was due.

Rashi was twenty-five years of age when he returned to Troyes, which town thenceforward eclipsed the cities of Lorraine and became the recognized centre of Jewish learning. Rashi acted as rabbi and judge, but received no salary. Not till the 14th century were Jewish rabbis paid officials. Rashi and his family worked in the vineyards of Troyes (in the Champagne); in his letters he describes the structure of the wine-presses. His learning and character raised him to a position of high respect among the Jews of Europe, though Spain and the East were long outside the range of his influence. As was said of him soon after his death: "His lips were the seat of wisdom, and thanks to him, the Law, which he examined and interpreted, has come to life again." His personality included several famous names, those of his grandchildren. Rashi had no sons, but his three daughters were women of culture, and two of the sons of Jochebed (see Rashbam and Talmud), as well as others of his descendants, carried on the family tradition for learning, adding lustre to Rashi's fame. The latter part of Rashi's life was saddened by the incidents connected with the first Crusade. Massacres occurred in the Rhineland. According to legend, Rashi and Godfrey of Bouillon—one of the foremost leaders of the Crusade—were intimate friends. Rashi died peacefully in Troyes in 1105.

Rashi was the most conspicuous medieval representative of the Jewish spirit. A century later Maimonides was to give a new turn to Jewish thought, by the assimilation of Aristotelianism with Mosaism, but Rashi was a traditionalist pure and simple. He was in no sense a philosopher, but he exemplified in his person and in his works the stored up wisdom of the Synagogue. Yet through all that he wrote there runs a vein of originality. Besides minor works, such as a recension of the Prayer-Book (Siddur), the Parades and ha-Orah, Rashi wrote two great commentaries on which his fame securely rests. These were the commentaries, on the whole of the Hebrew Bible and on about thirty treatises of the Talmud. His commentary on the Pentateuch, in particular, has been printed in hundreds of editions; it is still to Jews the most beloved of all commentaries on the Mosaic books. More than a
hundred supercommentaries have been written on it. Rashi unites homily with grammatical exegesis in a manner which explains the charm of the commentary. His influence in Christian circles was great, especially because of the use made of the commentary by Nicolaus de Lyra (q.v.), who in his turn was one of the main sources of Luther's version. Even more important was Rashi's commentary on the Talmud, which became so acknowledged as the definitive interpretation that Rashi is cited simply under the epithet of "the Commentator."

It is no exaggeration to assert that the modern world owes its power to understand the Talmud to Rashi. In this field the "Commentator" is supreme. He practically edited the text of the Talmud besides explaining it, and the Talmud is never printed without Rashi's commentary on the margin. An important feature of Rashi's commentaries is the frequency of French translations of words. These glosses (lo'azim) have now been in part edited from the manuscripts of the late Arsène Darmesteter.

**BIBLIOGRAPHY.**—M. Liber, *Rashi* (1906), published as a memorial of Rashi on the 800th anniversary of his death. Rashi's commentary on the Bible is contained in Latin by Breithaupt (1670-1714); and into German (Pentateuch) by Dukes (1833-38) and others. The foundation of recent investigation into Rashi's life is *Zunz's Salomon b. Isaac* (1823), to which I. H. Weiss added much in his (Hebrew) biography (in *Bet Talmud ii.*, Nos. 2-10. See also Graetz, *History of the Jews* (Engl. trans., vol. iii. ch. ix.). A critical edition of Rashi's Pentateuch commentary was published by A. Berliner (2nd ed., 1905).

**RASHTRAKUTA,** an Indian dynasty which ruled in the Deccan (q.v.) from about A.D. 750 to 973. The Rashtракутa or Ratta clan are supposed to have held power during the historical blank before the 6th century; but they came to the front in A.D. 750, when Dantidurga overthrew the Chalukya dynasty and made himself ruler of the Deccan. He was succeeded by his uncle Krishna I. (c. 760), who completed his conquests, and whose reign is memorable for the execution of the Kailasa, the rock-cut temple at Ellora. His grandson Govinda III. (780-815) extended the power of the family from the Vindhyan Mountains and Malwa on the north to Kanchi on the south. The next king, Amogavarsa, reigned for forty-two years. The reign of Krishna III. was remarkable for a war with the Cholas, in which the Chola king was killed on the field of battle in 949. The last of the Rashtракuta kings was Karka II., who was overthrown by the Chalukyas in 973.

**RASK, RASMUS CHRISTIAN** (1787-1832), Danish scholar and philologist, was born at Brondenke in the island of Fünen or Fyen in Denmark in 1787. He studied at the university of Copenhagen, and at once showed remarkable talent for the acquisition of languages. In 1808 he was appointed assistant keeper of the university library, and some years afterwards professor of literary history. In 1811 he published, in Danish, his *Introduction to the Grammar of the Icelandic and other Ancient Northern Languages*, from printed and MS. materials accumulated by his predecessors in the same field of research. The reputation which Rask thus acquired recommended him to the Arna-Magnaeana Institution, by which he was employed as editor of the Icelandic *Lexion* (1814) of Björn Haldorson, which had long remained in manuscript. Rask visited Iceland, where he remained from 1813 to 1815. mastering the language and familiarizing himself with the literature, manners and customs of the island. His exertions in this direction have been such as to inspire him may probably be attributed the establishment at Copenhagen, early in 1816, of the Icelandic Literary Society, of which he was the first president.

In October 1816 Rask left Denmark on a literary expedition, at the cost of the king, to prosecute inquiries into the languages of the East, and collect manuscripts for the university library at Copenhagen. He proceeded first to Sweden, where he remained two years, in the course of which he made an excursion into Finland to study the language. Here he published, in Swedish, his *Anglo-Saxon Grammar* in 1817. In 1818 there appeared at Copenhagen, in Danish, an *Essay on the Origin of the Ancient Scandinavian or Icelandic Tongue*, in which he traced the affinity of that idiom to the other European languages, particularly Latin and Greek. In the same year he brought out the first complete editions of Snorro's *Edda* and Saemund's *Edda*, in the original text, along with Swedish translations of both *Eddas*. From Stockholm he went in 1819 to St Petersburg, where he wrote, in German, a paper on "The Languages and Literature of Norway, Iceland, Sweden and Finland," in the sixth number of the *Vienna Jahrbücher*. From Russia he proceeded through Tartary into Persia, and resided for some time at Tabriz, Teheran, Persepolis and Shiraz. In about six weeks he made himself sufficiently master of Persian to be able to converse freely. In 1820 he embarked at Bushire for Bombay; and during his residence there he wrote, in English, "A Dissertation on the Authenticity of the Zend Language" (*Trans. Lit. Soc. of Bombay*, vol. iii., reprinted with corrections and additions in *Trans. R. As. Soc.*). From Bombay he proceeded through India to Ceylon, where he arrived in 1822, and soon afterwards wrote, in English, "A Dissertation respecting the best Method of expressing the Sounds of the Indian Languages in European Characters," in *The Transactions of the Bombay Society*. In 1823 he returned to Copenhagen. Rask returned to Copenhagen in May 1823, bringing a considerable number of Oriental manuscripts, Persian, Zend, Pali, Sinhalese and others, with which he enriched the collections of the Danish capital. He died at Copenhagen on the 14th of November 1832.

During the period between his return from the East and his death Rask published in his native language a *Spanish Grammar* (1824), a *Frisic Grammar* (1825), an *Essay on Danish Orthography* (1826), a *Treatise respecting the Ancient Egyptian Chronology and an Italian Grammar* (1827), and the *Ancient Jewish Chronology* (1828). He also edited an edition of Schneider's *Danish Grammar for the use of Englishmen* (1830), and superintended the English translation of his *Anglo-Saxon Grammar* by Thorpe (1830). He was the first to point out the connexion between the ancient Northern and Gothic on the one hand, and the Lithuanian, Scivlonic, Greek and Latin on the other, and he also deserves credit for having had the original idea of "Grimm's Law" for the transmutation of consonants in the transition from the old Indo-European languages to Teutonic, although he only compared Teutonic and Greek, Sanskrit being at the time unknown to him. In 1822 he was master of no less than twenty-five languages and dialects, and is stated to have studied twice as many. His numerous works are included in the catalogue of the *Royal Library at Copenhagen*. Rask's *Anglo-Saxon, Danish and Icelandic Grammars* were brought out in English editions by Thorpe, Repp and Duetsent respectively.

**RASPBERRY,** known botanically as *Rubus Idaeus* (nat. ord. Rosaceae, g.v.), a fruit-bush found wild in Great Britain and in woods throughout Europe, North Africa and in north and west Asia. The raspberry was known to classic writers, and is mentioned by Pliny as one of the wild brambles known to the Greeks as *Ideo*, from Mt. Ida in Asia Minor on which it grew. Parkinson (*Paradisius*, 1629) speaks of red, white and thornless varieties as suitable for the English climate, and Gerarde (*Herbal*, 1597) figures and describes the Raspis or Framboise bush as one of the four kinds of bramble. It is propagated from suckers, which may be taken off the parent stools in October, and planted in rows 5 or 6 ft. apart, and at 3 ft. asunder in the rows. It is the habit of the plant to throw up from the root every year a number of shoots or canes, which bear fruit in the subsequent year, and then decay. In dressing the plants, the new shoots are thus encouraged, the canes, if not wanted, are cut away, and of the young canes only three or four of the strongest are left, which are shortened about a third. The stems, being too weak to stand by themselves, are sometimes connected together by the points in the form of arches, or a stake is driven in midway between the plants, and half the canes are bent one way and half the other, both being tied to the stake. Sometimes they are tied upright to stakes fixed to each stool. The best support, however, is obtained by fastening the points of the shoots to a slight horizontal rail or bar, placed a foot and a half on the south side of the rows,
by which means the bearing shoots are deflected from the perpendicular to the sunny side of the row, and are not shaded by the annual wood. When this mode of training is adopted, the plan of planting 1 foot apart in the row and leaving one or two canes only to each shoot is preferable. The ground between the rows should never be disturbed by deep digging; but an abundant supply of good manure should be given annually in autumn in a dressing, which should be forked in regularly to a depth of 4 or 5 inches. All surplus suckers should be got away early in the summer before they have rooted the roots—five or six, to be reduced to the four best, being reserved to each root. Fresh plantations of raspberries should be made every six or seven years. The double-bearing varieties, which continue to fruit during autumn, require light soils and warm situations. These should be cut close down in February, as it is the strong young shoots of the current year which bear the late autumnal crops. The other varieties may be made to bear in autumn by cutting the stems half-way down at an early period in spring; but, as with all other fruits, the flavour of the raspberry is best when it is allowed to ripen at its natural season.

The following are some of the finer sorts now in cultivation:—
Baumforth's Seedling—a large summer-bearing red.
Carter's Prolific—a large summer-bearing red.
Fassiford or Fulbrook—a large summer-bearing red.
Flandin's Prolific—a large double-bearing red.
Northumberland Fulbasket—a large summer red.
October Red—a fine autumn-bearing red.
October Yellow—a fine autumn-bearing yellow.
Prince of Wales—a large summer-bearing red.
Red Antwerp—a large summer-bearing red.
Roger's Victoria—a large autumn-bearing red.
Round Antwerp—a large summer-bearing red.
Sémore Fidèle—an excellent bright red variety; heavy cropper.
Superlative—fruits rich red; perhaps the best raspberry in cultivation.
Sweet Yellow Antwerp—a large summer-bearing yellow.

The European raspberry, though admittedly of better quality, has been largely displaced in the United States of America by a closely allied native species, R. strigosus, the numerous varieties of which are harder than the varieties of the European species and ripen their crop much more rapidly. The stems are more slender and flexible than in R. Idaeus, usually brown or reddish-brown in colour and beset with stiff straight prickles. The most important raspberry of cultivation in America is R. occidentalis, the black raspberry or thimbleberry, which is at once distinguished by its firm black, rarely yellow, fruit. The purplish-cane raspberry, R. neglectus, with fruit varying in colour from dull purple to dark red or sometimes yellowish, is perhaps a hybrid between R. strigosus and R. occidentalis.

For a detailed account of the American species of Rubus see F. W. Card, Bush-fruits (1896).

The Loganberry is a hybrid between the raspberry (Rubus Idaeus) and the blackberry or bramble (R. fruticosus), and derives its name from its raiser, Judge Logan of the American Bar. It is a strong-growing plant, partaking more of the habit of the blackberry than the raspberry, and making shoots often 10 to 15 ft. long in the course of the year. These bear leaves with 5 leaflets, and fruit the following year. The flowering shoots have leaves with only 3 leaflets; but young and old stems are densely covered with sharp crimson prickles. The fruits are borne profusely in loose trusses, and are ripe in southern localities in July, and about early August in northern parts. They are at first reddish like raspberries in a half-ripened state, but when fully ripe are deep purplish red, and much more palatable, each fruit being about 1½ in. long, and shaped like a raspberry.

The Loganberry flourishes in heavy loamy soil, and is a useful plant for old fences or trellises, or even in waste places, where it is fully exposed to the sunshine. The old fruiting shoots should be cut away each winter, and in the spring the young shoots should have a foot or two taken off the ends, to induce the better and riper buds lower down to throw masses of white flowers, to be succeeded in due course by the fruits. Propagation is by means of suckers from the base.
RASTELL, J.—RASTELL, W.

by rail S.W. of Karlsruhe. Pop. (1905) 14,404. The old palace of the margraves of Baden, a large Renaissance edifice in red sandstone, is now partly used for military purposes and contains a collection of pictures, antiques and trophies from the Turkish wars. The chief manufactures are stoves, beer and tobacco. Until the end of the 17th century Rastatt was unimportant, but after its destruction by the French in 1689 it was rebuilt on a larger scale by Louis William, margrave of Baden, the imperial general in the Turkish wars. It was then the residence of the margraves until 1771. The Baden revolution of 1849 began with a mutiny of soldiers at Rastatt in May 1849, and ended here a few weeks later with the capture of the town by the Prussians. For some years Rastatt was one of the strongest fortresses of the German empire, but its fortifications were dismantled in 1896.

See Schuster, Rastatt, die ehemalige badische Residenz und Bundesfestung (Lahr, 1902); and Lederer, Rastatt und seine Umgebung (Rastatt, 1905).

Rastatt has been the scene of two congresses. At the first congress, which was opened in November 1734, negotiations were carried on between France and Austria for the purpose of ending the war of the Spanish succession. These culminated in the treaty of Rastatt signed on the 7th of March 1714. The second congress, which was opened in December 1797, was intended to rearrange the map of Germany by providing compensation for those princes whose lands on the left bank of the Rhine had been seized by France. It had no result, however, as it was ended by the outbreak of the European war, but it had a sequel of some interest. As the three French representatives were leaving the town in April 1799 they were waylaid, and two of them were assassinated by some Hungarian soldiers. The origin of this outrage remains shrouded in mystery, but the balance of evidence seems to show that the Austrian authorities had commanded their men to seize the papers of the French plenipotentiaries in order to avoid damaging the reputation of Austria which was lending on Bavaria, and that the soldiers had exceeded their instructions. On the other hand, some authorities think that the deed was the work of French emigrants, or of the party in France in favour of war.

For fuller particulars of the two sides of this controversy see K. Mendelsohn- Bartholdy, Der Rastatter Gesandtenord (Heidelberg, 1896); J. A. Freiherr von Hellert, Der Rastatter Gesandtenord (Vienna, 1874); Böcking-Prietz, Nachrichten der Rastatter Gesandtenord (Jena, 1890); and Zehrer, Rastatter Gesandtenord (Heidelberg, 1895); H. Hüffer, Der Rastatter Gesandtenord (Bonn, 1896); and H. von Sybel, in Band 39 of the Historische Zeitschrift.

RASTELL (or RASTALL), JOHN (d. 1536), English printer and autho, was born in London towards the end of the 15th century. He is vaguely reported by Anthony a Wood to have been "educated for a time in grammatical and philosophical" at Oxford. He became a member of Lincoln's Inn, and practiced successfully as a barrister. He was also M.P. for Dunheved, Cornwall, from 1529 to 1531. He began his printing business some time before 1516, for in his preface to the undated Liber Assurarium he announced the forthcoming publication of Sir A. Fitzherbert's Abbrevidation librarium legum Angliae, dated 1516. Among the works issued from his press were: The Meri Gestyts of the Wydow Edyht (1525), and A Dyalogy of Sir Thomas More (1529). The last of his dated publications was Fairby's Ghoste (1533), a poem. In 1530 he wrote, in defence of the Roman doctrine of Purgation, A New Boke of Purgatoury (1530), dialogues on the subject between "Coynys and Almayn a Christen man, and one Gyngemyn a Turke." This was answered by John Frith in A Disputation of Purgatourie. Rastell replied with an Apology against John Frith, also answered by the latter. Rastell had married Elizabeth, sister of Sir Thomas More, with whom his Catholic theology and political views came into sympathy. More had begun the controversy with John Frith, and Rastell joined him in attacking the Protestant writer, who, says Foxe (Actes and Monumentes, ed. G. Townsend, vol. v. p. 9), did so "overthrow and confound " his adversaries that he converted Rastell to his side. Separated from his Catholic friends, Rastell does not seem to have been fully trusted by the opposite party, for in a letter to Cromwell, written probably in 1536, he says that he had spent his time in upholding the king's cause and opposing the pope, with the result that he had lost both his printing business and his legal practice, and was reduced to poverty. He was imprisoned in 1536, perhaps because he had written against the payment of tithes. He probably died in prison, and his will, of which Henry VIII. had originally been appointed an executor, was proved on the 18th of July 1536. He left two sons: William, noticed below, and John. The Jesuit, John Rastell (1532–1577), who has been frequently confounded with him, was no relation.

Rastell's best-known work is The Pastyme of People, the Chron-}
RASTENBURG—RATEL

915

RASTENBURG, a town of Germany, in the province of East Prussia, lying in a flat sandy plain on the Guber, 64 m. S.E. of Königsberg by the railway to Prostken. Pop. (1905) 11,889. Its principal manufactures are flour, sugar, oil, beer and machinery. In the vicinity is Karlshof, a celebrated establishment for the cure of epileptic diseases.

See Beckherrn, Mittheilungen aus Rastenburgs Vergangenheit (Rastenburg, 1891); and Schaffer, Chronik von Rastenburg (Rastenburg, 1889).

RAT (a word common to Teut. and Rom. languages; probably first adopted in Teut.; the ultimate origin is not known; Skeit suggests the root rot-, to scratch; cf. Ger. Ratte, Dan. rotte, Fr. rat, &c.), probably in its original sense the designation of the British rodent mammal commonly known as the black rat (Mus rattus), but also applied indifferently to the brown or Norway rat (M. norvegicus), and in a still wider sense to all the larger representatives of the genus Mus, as to many other members of the family Muridae. In fact, as mentioned in the article Mouse, there is no possibility of defining the term “rat” when used in a sense other than as relating to the two species above mentioned; while there is also no hard-and-fast limit between the terms “rats” and “mice” when these are likewise employed in their now extended sense, “rats” being merely larger “mice,” and vice versa. Rats have, however, generally more rows of scales on the tail (reaching to 210 or more) than mice, in which the number does not exceed 180. For the distinctive characteristics of the family Muridae and the genus Mus, to which true rats and true mice alike belong, see Rodentia. Of the two British species the brown, or Norway rat (M. norvegicus) is distinguished by its large size, brownish grey colour, short tail and ears, stout skull, and the possession of from 10 to 12 teats. It is fierce and cunning, and easily overcomes all allied species with which it is brought in contact. Its original home would seem to have been some part of Central Asia, an indigenous species from China. M. humilis, being so like it that in all probability the latter is the original race from which it has sprung. Thence it has spread to all parts of the world, driving out the house-hunting species weeded out as has in England all but exterminated the black rat. The brown rat migrated westwards from Central Asia early in the 18th century, and is believed to have first reached Great Britain about 1730. Its already evil reputation has been increased of late years by the fact that it is one of the chief disseminators of bubonic plague. Black phases are not uncommon. The black rat (M. rattus) is distinguishable from the brown rat by its smaller size, longer ears and tail, and glossy black colour. It shares the ravaging habits of the latter, frequenting ships and by these means reaching various parts of the world. On this account either the typical form or the tropical M. rattus alexandrinus is common in many places to which the brown species has not yet penetrated, for instance in South America. This long-tailed rat, originally a native of India, would seem to have first penetrated to all parts of the world and to have nearly or quite exterminated the indigenous rats. After this followed the advance of the more powerful brown rat. The black rat first reached Europe in the 13th century, but of late years another and still darker phase of the species, the Black Sea black rat (M. rattus alger) made its appearance in England. The Isle of Dogs and Yarmouth, in Norfolk, are reported to be the chief of the English strongholds of the black rat. Both species agree in their predaceous habits, omnivorous diet and great fecundity. They bear, four or five times in the year, from four to ten blind and naked young, which in their turn able to breed at an age of about six months; the time of gestation being about twenty days.

RATAFIA, a liqueur or cordial flavoured with peach or cherry kernels, bitter almonds, or other fruits; many different varieties are made. The same name is given to a flavouring essence resembling bitter almonds, and also to a light biscuit. The word is adapted from the French of the 17th century. Skeit (Etym. Dict., 1910) quotes as a possible origin a combination of Malay ara, arac and latja, rum.

Rate, a general term for proportion, standard, allowance, tax. Lat. rate, from pro rata parte, ratus being the participle of reri, to think, judge. In England the term is specially applied to the levying of public money contributions for local purposes, as distinguished from the “taxes” raised for what are treated as general state purposes. The money required for local administration in England is raised (when the ordinary revenues are insufficient) by assessments on lands and buildings based on their annual rental value. The financial authority estimates what additional amount beyond revenue is required for the expenses of administration, and levies a rate to meet it. The earliest rate levied in England was that for poor relief, and of the great variety of rates now existing, the majority are based on the poor rate and levied with it, under the term of precept rates. Next to the poor rate came that for highways, and other special rates have been authorized from time to time, as for police, education, public lighting, cemeteries, libraries, sanitary purposes, &c. To distinguish the rate the name of the precepting authority is frequently added or the purpose for which it is levied specified, or county rate, watch rate, &c.

The valuation list of a parish is the basis on which the poor rate is levied. This valuation list contains the gross estimated rental and rateable value of all rateable property in the parish. The gross estimated rental is the rent at which a property might reasonably be expected to let from year to year, the tenant paying tithes, rates and taxes. From this is deducted the average annual cost of repairs, insurance and renewals, the balance constituting the rateable value. The rateable value of the parish being known, so much on each pound of the rateable value as will equal the amount required to be raised is levied, and is known as the “rate.” See further England, Local Government; Taxation.

Rating, in maritime vocabulary, is the classification of men according to rank, and was formerly employed to class ships of a navy according to strength. A sailor is said to be “rated A.B.,” “in the navy,” “rated petty officer,” “seaman,” “gunner” and so on. The rating of ships begins in the 17th century, and was at first done roughly by size and number of crew. Later the rating was by guns. Thus in 1741 in the British navy there were six rates: 1st, 100 guns; 2nd, 90; 3rd, 70 to 80; 4th, 50 to 60; 5th, 40; and 6th, 20. Sloops, fire ships, bomb-vessels and royal yachts were said to be not rated. The classification of ships into six rates, and into rated and non-rated ships, continued during the existence of the old sailing fleets, with modifications in detail. The practice of other navies was similar to the British.

RATEL, or HONEY-BADGER, the name of certain Indian and African small clumsy-looking creatures of about the size and appearance of badgers, representing the genus Mellivora in the family Mustelidae (see Carnivora). Two species of ratel are commonly recognized, the Indian (M. indica), and the African (M. ralat), which ranges over Africa, but a black ratel from the Ituri forest has been separated as M. cottoni. Both the two former are iron-grey on the upper parts, and black below, a style of coloration rare among mammals, as the upper side of the body is in the great majority darker than the lower.
The body is stout and thickly built; the legs are short and strong, and armed, especially the anterior pair, with long curved claws; the tail is short; and the ears are reduced to rudiments. The skull is conical, stout and heavy, and the teeth, although sharper and less rounded than those of badgers, are less suited to a carnivorous diet than those of stoats, weasels and martens. The two ratels may be distinguished by the fact that the African species has a distinct white line round the body at the junction of the grey of the upper side with the black of the lower, while in the Indian this line is absent; the teeth also of the former are larger, rounder and heavier than those of the latter. The two are, however, so nearly allied that they might almost be considered geographical races of a single species. Dr T. C. Jerdon states that the Indian ratel is found throughout the whole of India, from the extreme south to the foot of the Himalaya, chiefly in hilly districts, where it has greater facilities for constructing the holes and dens in which it lives; but also in the north of India in alluvial plains, where the banks of large rivers afford equally suitable localities wherein to make its lair. It is stated to live usually in pairs, and to eat rats, birds, frogs, white ants and various insects, and in the north of India it is accused of digging out dead bodies, and several of the native names mean "grave-digger." Dr W. T. Blanford, in the *Fauna of British India*, is of opinion that thelero is without foundation. Like its Cape congener it occasionally partakes of honey, and is often destructive to poultry. In confinement the Indian ratel becomes tame and even playful, displaying a habit of tumbling head over heels.

(R. L.)

**RATH, GERHARD VOM** (1830-1888), German mineralogist, was born at Dinsburg in Prussia, on the 20th of August 1830. He was educated at Cologne, at Bonn University, and finally at Berlin, where he graduated Ph.D. in 1853. In 1856 he became assistant to Nögerath in the mineralogical museum at Bonn, and succeeded to the directorship in 1872. Meanwhile in 1862 he was appointed extraordinary professor of geology, and in 1872 he became professor of geology and mineralogy in the university at Bonn. He was distinguished for his accurate researches in mineralogy and crystallography; he described a great many new minerals, some of which were discovered by him, and he contributed largely to our knowledge of other minerals, notably in an essay on tridymite. He travelled much in southern Europe, Palestine and the United States, and wrote several essays on petrology, geology and physical geography, on earthquakes and on meteorites. He died at Coblenz on the 23rd of April 1888.

His separate publications included *Ein Ausflug nach Kalabrien* (1871); *Der Moinzi im südöstlichen Tirol* (1875); and *Durch
very different from that of the early and medieval Church. Rationalism within the Christian Church differs, however, from that which is commonly understood by the term, inasmuch as it accepts as revealed the fundamental facts of its creed. Thoroughgoing rationalism, on the other hand, either categorically denies that the supernatural or the infinite—whether it exist or not—can be the object of human knowledge (see AGnosticism), or else, in the mouth of a single person, states that he at least has no such knowledge. In addition to the difficulties presented by the Bible as an historical record, and the literary problems which textual and other critics have investigated, the modern freethinker denies that the Christianity of the New Testament or its interpretation by modern theologians affords a coherent theory of human life and duty. Apart from the general use of the term for a particular attitude towards religion, two more technical uses require notice: (i) the purely philosophical, (ii) the theological.

(i) Philosophical rationalism is that theory of knowledge which maintains that reason is in and by itself a source of knowledge, and that knowledge so derived has superior authority over knowledge acquired through sensation. This view is opposed to the various systems which regard the mind as a tabula rasa (blank tablet) in which the outside world as it were imprints itself through the senses. The opposition between rationalism and sensationalism is, however, rarely so simple and direct, inasmuch as many thinkers (e.g. Locke) have admitted both sensation and reflection. Such philosophies are called rationalist or sensationalist according as they lay emphasis specially on the function of reason or that of the senses. More generally, philosophical rationalism is opposed to empirical theories of knowledge, inasmuch as it regards all true knowledge as deriving deductively from fundamental elementary concepts. This attitude may be studied in Descartes, Leibnitz and Wolff. It is based on Descartes' fundamental principle that knowledge must be clear, and seeks to give to philosophy the certainty and demonstrative character of mathematics, from the a priori principle of which all its claims are derived. The attack made by David Hume on the causal relation led directly to the new rationalism of Kant, who argued that it was wrong to regard thought as mere analysis. A priori concepts there are, but if they are to lead to the amplification of knowledge, they must be brought into relation with empirical data.

(ii) The term “rationalism” in the narrow theological sense is specially used of the doctrines held by a school of German theologians and Biblical scholars which was prominent roughly between 1740 and 1836. This rationalism within the Church was a theological manifestation of the intellectual movement known as the Enlightenment (Aufklärung), and must be studied in close connexion with the purely philosophical rationalism already discussed. It owed much to the English deists, to the Pietistic movement, and to the French esprits forts who had already made a vigorous attack on the supernatural origin of the Scriptures. The crux of the difficulty was the doctrine of the supernatural, the relation between revealed and natural religion. The first great rationalist leader was J. S. Semler (q.v.), who held that true religion springs from the individual soul, and attacked the authority of the Bible in a comprehensive spirit of criticism. He ultimately reached a point at which the Bible became for him simply one of many ancient documents. At the same time he did not impugn the authority of the Church, which he regarded as useful in maintaining external unity. Among those who followed in Semler's path were Gruner Ernesti, J. D. Michaelis, Griesbach, J. G. Eichhorn. This spirit was exhibited on the philosophical side by Kant who in Die Religion innerhalb der Grenzen der blossen Vernunft (1793) set forth his doctrine of rational morality (Veranschlichung) as the only true religion. These two great rationalist movements, the critical and the philosophical, ultimately led to, or were accompanied by, the gradual reduction of religion to a system of morals based at the most on two or three fundamental religious principles. This is the rationalism known as rationalismus vulgaris, the period of which is practically from 1800 to 1813. Among its exponents were Wegscheider, Bretschneider and H. E. G. Paulus (q.v.). The general attitude of German theology, however, became gradually more and more hostile, and the works of Schleiermacher, though in a sense themselves rationalist, renewed the general desire for a positive Christianity. Hase's Hortus Redivivus, an exposition of orthodoxy in the light of modern development, called forth a final exposition of the rationalist position by Röhr. From that time the school as such ceased to have a real existence, though the results of its work are traceable more or less in all modern Biblical criticism, and its influence upon the attitude of modern theologians and Biblical critics can scarcely be overestimated.

Ratisbonne—Ratisia

RATISBONNE, LOUIS GUSTAVE FORTUNÉ (1827-1900), French man of letters, was born at Strassburg on the 29th of July 1827. He studied at the school of his native town and at the Collège Henry IV. in Paris. He was connected with the Journal des Débats from 1853 to 1876; became librarian of the palace of Fontainbleau in 1871, and three years later to the Senate. Louis Ratisbonne's most important work was a verse translation of the Divine Commedia, in which the original is rendered tercet by tercet into French. L'Enfer (1852) was crowned by the Academy; Le Purgatoire (1857) and Le Paradis (1859) received the prix Bordin. He is also the author of some charming fables and verses for children: La Comédie enfantine (1866), Les Figures jeunées (1865) and others. He was literary executor of Alphonse de Lamartine, whose Destinées (1864) and Journal d'un poète (1865) he published. Ratisbonne died in Paris on the 24th of September 1900.

RATITAE (from Lat. ratis, a raft), the name given by B. Merrem (Abh. Ak. Wiss., Berlin, 1812-1813; Phys. Kl., p. 250) to the “flat-breasted birds,” in opposition to the Carinatae, or those which normally possess a keeled sternum. In thus dividing the birds into two great equivalent groups, he was followed only by C. L. Nitzsch (1829), T. H. Huxley (1867), P. L. Sclater (1880), A. Newton (1884), R. B. Sharpe (1891), whilst in most of the other numerous classifications the Ratitae (varicously named Struthiones, Cursores, Brevipennes, Proceres) were treated as of much lower rank.

A diagnosis covering all the Ratitae (struthio, rhea, casuarius, dromaeus, apilerix and the allied fossils dinornis and aepyornis) would be as follows—(i) terrestrial birds without keel to the sternum, absolutely flightless; (ii) quadrate bone with a single proximal articulating knob; (iii) coracoid and scapula fused together and forming an open angle; (iv) normally without a pygostyle; (v) with an incisura ischiadica; (vi) rhampletho compound; (vii) without apertillae or bare spaces in the plumage; (viii) with a complete copulatory organ, moved by skeletal muscles.

The separation of the Ratitae from the other birds, and their seemingly fundamental differences, notably the absence of the keel and of the power of flight, induced certain authors to go so far as to derive the Ratitae from the Dinosaurian reptiles, whilst Archaeopteryx (q.v.) and the Carinatae were supposed to have sprung from some Pterosaurian or similar reptilian stock. Such vagaries require no refutation. But it is quite another question, whether the “Ratitae” form a natural group. Sir R. Owen was the first (Comp. Anat. and Physiol. of Vertebrates, ii. 1866) to indicate that the various Ratitae might be referable to various natural groups of the Carinatae. A. W. Forbes likewise had doubts about them. B. Lindsay (P. Z. S., 1885, pp. 684-716, pls. ii.-iv.) found vestiges of a keel in a young rhea, and apertilia in the embryonic ostrich, and she concluded that they were descendants of birds which originally possessed
RATKE—RATON

the power of flight. This has been settled by M. Fürbringer (Untersuchungen . . . 1888), and there is now no doubt that the absence of the power of flight is a secondary, not primitive, feature in the Ratitae as well as in the flightless boma fide Carinatae, e.g. Didxus, and penguins. It had already been understood that the various genera of the Ratitae were the representatives of so many different groups, each of which was at least equivalent to ordinal rank, and that therefore, if the Ratitae were still to be considered a natural group, this common ancestry must be referred to a remote geological epoch. Fürbringer, however, separated Apteryx with Dinornis from the rest, combining his "Apteryges" with Crypturi and Galli as Alectorornithes, the latter being practically A. H. Garrard's Galliformes, of which his "Struthions" form part together with the Tinamidae or Crypturi. Relationship of this otherwise typically carinate, neotropical family with the Ratitae had already been insisted upon by T. H. Huxley; hence his term Dromeognathae for the Crypturi. L. Stejneger (Standard Nat. Hist., iv., Boston, 1885) applied this term in a new wider sense to all the Ratitae, and recently W. F. Pyrcraft has revived this notion by his division of the Neornithes into Dromeaco- and Neognathae. At any rate we begin to see that both the Ratitae and the Apteryges, perhaps, were early and have been after which modified offshoot of such of the Carinatae as are now represented by the Crypturi, whilst in another part of the world, and at a much later time, kiwis and moas have sprung from a somewhat more Galliform stock, which points to a descent from a still undivided Galliform-Tinamiform mass. Further, it is the opinion of competent ornithologists that there is affinity of the Australian emus and cassowaries with the New Zealand moas and with the Malagasy Aepyornis. Struthio alone still stands aloof, possibly because it is the oldest and most specialized form. This genus was already typically developed in late Miocene times, and with a very wide geographical distribution (see Bird, Fossil), but of the affinities of the other mid- and early tertiary flightless birds we know nothing, and it must be emphasized that we should probably not be able to classify a truly ancestral Ratite, namely, a bird which is still to a certain extent carinate and not yet ratite. It is impossible to give a satisfactory diagnosis of such intermediate forms.

While the Ratitae still possess a considerable number of rather primitive characters, e.g. they are typically nidifugous; the simple structure of their neossiptiles; quincubital; compound rhamphotheca; holarhin al naria imperviae; bapitrogen processes; simple articular facet of the quadrate; configuration of the palatal bones, including the large vomer; incisura ischiadica; simple hypotarsus; the thigh muscles; the copulatory organ.

We restrict the origin of the Ratitae to that great branch of still primitive Carinatae which, after separation of the Ratitae, has further developed into the legion of the Alectorornithae, notably Tinami- and Galliformes, together with still gruiforms (see Bird, Classification). From such a rudis indigestaque males, after it had attained an almost world-wide distribution, have arisen the various Ratitae, independently at various epochs and in various countries. Most of them are now restricted to widely separated countries of the southern hemisphere. Although loss of flight (correlated with more or less reduction of the wings and the sternal keel, and often compensated by the swimming limbs) has occurred, and is still taking place in various groups of birds, it is quite impossible that a new Ratite can still come into existence, because the necessary primitive substratum, whence arose the true Ratitae, is no longer available. Consequently we are justified in retaining "Ratite" in our classification, although they are a heterogeneous, not strictly monophyletic, assembly.

RATKE (RATCHIUS), WOLFGANG (1572-1635), German educationist, was born at Wilster, Holstein, on the 18th of October 1572, and educated at the university of Rostock. His system of education was based upon Bacon's philosophy, the principle being that of "proceeding from things to names," from the particular to the general, and from the mother tongue to foreign languages. In 1618 he opened schools at Augsburg and elsewhere, but to Kühlen difficulties with the clergy led to his imprisonment for eight months, and after starting another school at Magdeburg in 1620 which failed, he became a wanderer and died at Erfurt on the 27th of April 1635. His ideas were far in advance of his time, but he lacked executive ability.

RATLAM (or RUTLAM), a native state of central India, in the Malwa agency. Area, 902 sq. m. Its territory is closely interlaced with that of Sillana. It is held as tributary to Sindhia; but in 1819 an arrangement was made by which Sindhia engaged never to send any troops into the country or to interfere with the internal administration, and in 1861 the tribute was assigned to the British government in part payment of the Gwalior contingent. The population in 1901 was 83,773, showing a decrease of 6% in the decade; estimated revenue, £134,000; tribute, £2850. The chief, whose title is raja, is a Rahort Rajput of the Jodhpur family. The chief Sujjan Singh succeeded in 1893, and attained full powers in 1898. The town of Ratlam is 1577 ft. above sea-level. Pop. (1901) 36,321.

It is a junction on the Rajputana-Malwa railway, and an important centre of trade, especially in opium. The town of Ratlam is situated 120 m. N.N.E. of the city of Indore in the southern division of Bombay. The town is on the seacoast, 136 m. S. of Bombay. Pop. (1901) 16,904. A leading industry is the sardine fishery, which usually takes place in January and February, and engages fleets of canoes.

The District of Ratnagiri has an area of 3998 sq. m. It forms a strip between the western Ghats and the sea, and its general character is rugged; nearly all the fertile land lies on the banks of the streams which intersect the country. The coast, about 150 m. in length, is almost uniformly rocky and dangerous. At intervals of about 10 m. a river or bay opens, sufficiently large to form a secure harbour for native craft, and the promontories at the river mouths are almost invariably crowned with the ruins of an old fort. The rivers and creeks are generally navigable for about 20 m., and afford facilities for a coasting trade. At the beginning of British rule there were no roads, and traffic was confined to places where there was water carriage, but a network of roads has been made, opening communications by hill passes with the Deccan. Ratnagiri forms part of the Western Ghats of the southern ranges of the Western Ghats, and is annexed to the Indian empire by the British government in 1818 on the overthrow of Baji Rao. In 1901 the population was 1,167,927, showing an increase of 6% in the decade. Ratnagiri is the home of the influential class of Chitpavan Brahmans. It also supplies factory hands to Bombay and sepoys to the native army.

RATNAPURA (i.e. "The City of Gems"), the chief town in the province of Sabaragamuwa, Ceylon. It is the centre of a long established industry in digging for precious stones—rubies, sapphires, cat's-eyes, &c. There is also much rice and fruit cultivation and planting of tea in the district. Pop. of town (1901) 4064; of district 132,964.

RATON, a city and the county seat of Colfax county, New Mexico, U.S.A., in the N.E. part of the state, and about 193 m. by rail N.E. of Santa Fé. Pop. (1890) 1255; (1900) 3540 (337 foreign-born); (1910 census) 4539. Raton is served by the Atchison, Topeka & Santa Fé, the Saint Louis, Rocky Mountain & Pacific, and the Santa Fé, Raton & Eastern railways. The city lies immediately W. of the Raton Mountains, from which it derives its name, and has an elevation of 6400-6650 ft. above the sea. Among its institutions are a miners' hospital, maintained by the state, and a picturesque public park. The city lies within the Raton coal field, a southern continuation of the field of the same name in Colorado, and the richest coal-producing area in New Mexico. In 1907 70% of the total coal product of New Mexico came from Colfax county, in which this field is situated. Ores of gold, silver and lead have been mined in Colfax county. South and east of the city there is good farming land. Raton is a place of railway origin, and owes its development to its extensive railway shops, as well as to the proximity of mines. It was incorporated in 1891.
RATRAMNUS (d. c. 868), a theological controversialist of the second half of the 9th century, was a monk of the Benedictine abbey of Corbie near Amiens, but beyond this fact very little of his history has been preserved. He is best known by his treatise on the Eucharist (De corpore et sanguine Domini liber), in which he controverted the doctrine of transubstantiation as taught in a similar work by his contemporary Radbertus Paschasius. Ratramnus sought in a way to reconcile science and religion, whereas Radbertus emphasized the miraculous. Ratramnus’s views failed to find acceptance; their author was soon forgotten, and, when the book was condemned at the synod of Vercelli in 1059, it was described as having been written by Johannes Scotus Erigena at the command of Charlemagne. In the Reformation it again saw the light; it was published in 1532 and immediately translated. In the controversy about election, when appealed to by Charles the Bald, Ratramnus wrote two books De predestinatone Dei, in which he maintained the doctrine of a twofold predestination; nor did the fate of Gottschalk deter him from supporting his view against Hincmar as to the orthodoxy of the expression “trina Deitas.” Ratramnus perhaps won most glory in his own day by his Contra Graecorum opposita, in four books (868), a valued contribution to the controversy between the Eastern and Western Churches which had been raised by the publication of the encyclical letter of Photius in 867. An edition of De corpore et sanguine Domini was published at Oxford in 1859.

See the article by G. Steitz and Hauck in Hauck’s Realencyklopädie für protest. Theologie, Band xvi. (Leipzig, 1905); Naegle, Ratramnus und die heilige Eucharistie (Vienna, 1903); Schnitzer, Berengar von Tours; and A. Harnack, History of Dogma, v., pp. 309–312 (1894–9).

RATTAZZI, URBANO (1808–1873). Italian statesman, was born on the 20th of June 1808 at Alessandria, and from 1838 practised at the bar. In 1848 he was sent to the chamber of deputies in Turin as representative of his native town. By his debating powers he contributed to the defeat of the Balbo ministry, and for a short time held the portfolio of public instruction; afterwards, in the Gioberti cabinet, he became minister of the interior, and on the retirement of the last-named in 1849 he became practically the head of the government. The defeat at Novara compelled the resignation of Rattazzi in March 1849. His election as president of the chamber in 1852 was one of the earliest results of the so-called “commumio” with Cavour, i.e. the union of the moderate men of the Right and of the Left; and having become minister of justice in 1853 he carried a number of measures of reform, including that for the suppression of certain of the monastic orders. During a momentary reaction of public opinion he resigned office in 1858, but again entered the cabinet under La Marmora in 1859 as minister of the interior. In consequence of the negotiations for the cession of Nice and Savoy he again retired in January 1860. He was entrusted with the formation of a new ministry in March 1862, but in consequence of his policy of repression towards Garibaldi at Aspromonte he was driven from office in the following December. He was again prime minister in 1867, from April to October. He died at Frosinone on the 5th of June 1873. His wife, whom he married in 1856, was a remarkable woman. She was the daughter of Sir Thomas Wyse, British plenipotentiary at Athens, and Laetitia Bonaparte, niece of Napoleon I. Born in Ireland in 1833, she was educated in Paris, and in 1858 married a rich Alsatian named Solms; but the prince-president refused to recognize her, and in 1852 she was expelled from Paris. Her husband died soon after; and calling herself the Princesse Marie de Solms, she spent her time in various fashionable places and dabbled in literature, Eugène Sue and François Ponsard being prominent in her court of admirers. She published Les Chansons de l'exilée (1859) and some novels. After Rattazzi’s death, she married (1877) a Spaniard named Rute; she died in February 1902.

See Madame Rattazzi, Rattazzi et son temps (Paris, 1881); Bolton King, History of Italian Unity (London, 1899).

Rattlesnake. Rattlesnakes are a small group of the sub-family of pit-vipers (Crotalinae, see Snakes; Viperidae), characterised by a tail which terminates in a chain of horny, loosely connected rings, the so-called “rattle.” The “pit” by which the family is distinguished from the ordinary vipers is a deep depression in the integument of the sides of the snout, between the nostrils and the eye; its physiological function is unknown. The rattle is a complicated and highly specialized organ, developed from the simple conical scale or epidermal spine, which in the majority of snakes forms the termination of the general integument of the tail. The bone by which the root of the rattle is supported consists of the last caudal vertebra, from three to eight in number, which are enlarged, dilated, compressed and coalesced (fig. 1, a). This bone is covered with thick and vascular cutis, transversely divided by two constrictions into three portions, of which the proximal is larger than the median, and the median much larger than the distal. This cuticular portion constitutes the matrix of a horny epidermoid covering which closely fits the shape of the underlying soft part and is the beginning of the rattle, as it appears in young rattlesnakes before they have shed their skin for the first time. When the period of a renewal of the skin approaches a new covering of the extremity of the tail is formed below the old one, but the latter, instead of being cast off with the remainder of the epidermis, is retained by the posterior swelling of the end of the tail, forming now the first loose joint of the rattle. This process is repeated on succeeding molts— the new joints being always larger than the old ones as long as the snake grows. Perfect rattles therefore taper towards the point, but generally the oldest (terminal) joints wear away in time and are lost. As rattlesnakes shed their skins more than once every year, the number of joints of the rattle does not indicate the age of the animal but the number of exuviations which it has undergone. The largest rattle in the British Museum has twenty-one joints. The rattle consists thus of a variable number of dry, hard, horny cup-shaped joints, each of which loosely grasps a portion of the preceding, and all of which are capable of being shaken against each other. If the interspaces between the joints are filled with water, as often happens in wet weather, no noise can be produced. The motor power lies in the lateral muscles of the tail, by which a vibratory motion is communicated to the rattle, the noise produced being similar to that of a child’s rattle and perceptible at a distance of from 10 to 20 yds.

The habit of agitating the tail is not peculiar to the rattlesnake, but has been observed in other venomous and innocuous snakes with the ordinary tail, under the influence of fear or anger. It is significant that the tip of such snakes is sometimes rather conspicuously coloured and covered with peculiarly modified...
scales, notably in *Acanthophis*. The use of such a tail probably consists in attracting or fixing the attention of small animals, by slightly raising and vibrating the tip. The rattle no doubt acts as a warning, every snake preferring being left alone to being forced to bite. Many a man has been warned in time by the shrill sound, and this principle applies undoubtedly to other

mammals. Moreover, rattlesnakes are rather sluggish, and comparatively not vicious. First they try to sink away; when overtaken or cornered they use every means of frightening the foe by swelling up, puffing, rattling and threatening attitudes; it is as a rule not until they are touched, or provoked by a rapid movement, that they retaliate, but then they strike with fury. They are viviparous, and as destroyers of rats, mice and other small rodents they are useful. The surest way of clearing a ground of them and any other snakes is to drive in pigs, which are sure to find and to eat them, without harm to themselves. They inhabit localities to which the sun has free access, prairies, rough stony ground, &c. Specimens of 5 ft. in length are not rare. Formerly common in the eastern parts of the United States, and still so in thinly inhabited districts, rattlesnakes, like the vipers of Europe, have gradually succumbed to the persecution of man.

Rattlesnakes are confined to the New World. North-American authors distinguish a great number of different kinds, S. W. Garman (*Reptiles and Batrachians of North America,* Harvard Mus. Zool. Mem., 1883, 4to) enumerating twelve species and thirteen additional varieties. E. D. Cope has split them into twenty; but all these species or varieties fall into two groups. One, *Sistrurus*, has the upper side of the head covered with the ordinary nine shields; only three species, of comparatively small size, in North America

(*Sistrurus miliarius* from Florida to Sonora; *S. catenatus* in many of the middle states of the Union, and elsewhere, as far north as Michigan; *S. raus* in Mexico).

The second group forms the genus *Crotalus*, in which the shields between and behind the eyes are broken up and replaced by small scales. This genus ranges throughout the United States through Central and South America into Patagonia, but is not represented on any of the West Indian islands. *C. horridus*, with the tail uniformly black, from Maine to Kansas and Louisiana to Florida. *C. adamanteus*, tall light, with black crossbands, body with a hand-some pattern of rhombs with lighter centres and yellowish edges; chiefly south-eastern states, to Arizona and Mexico; the largest of rattlers, giants of 8 ft. *C. leucomelas*, light brown, with black bands; *C. durissus*, light tail, with black crossbands; with a continuous series of large brown or reddish rhomboidal spots on the back; Texas to California. *C. cerastes*, with a pair of horns above the eyes; the "sidewinder" of Arizona and California. *C. lachesis*, easily distinguished by the possession of three pairs of symmetrical shields on the top of the muzzle, ranging from Arizona into Argentina. It is the only kind of rattlesnake in Central and South America. *C. triseriatus*, a small species, with a feeble developed rattle, on Mexican mountains, on the pic of Orizaba up to 12,500 ft.

(ST G. M.; H. F. G.)
RAUCH—RAUPACH

RAUCH, CHRISTIAN DANIEL (1777–1857), German sculptor, was born at Arolsen in the principality of Waldeck on the 2nd of January 1777. His parents were poor and unable to place him under efficient masters. His first instructor taught him little else than the art of sculpturing gravestones, and Professor Ruhl of Cassel could not give him much more. A wider field of instruction opened up before him when he removed to Berlin in 1792, but he was obliged to earn his livelihood by becoming a royal lackey, and to practise his art in spare hours. Queen Louisa, surprising him one day in the act of modelling her features in wax, sent him to study at the Academy of Art. Not long afterwards, in 1804, Count Sandrexy gave him the means to complete his education at Rome, where William von Humboldt, Canova and Thorwaldsen befriended him. Among other works, he executed bas-reliefs of "Hippolytus and Phaedra," "Mars and Venus wounded by Diomede," and a "Child praying." In 1811 Rauch was commissioned to execute a monument for Queen Louisa of Prussia. The statue, representing the queen in a sleeping posture, was placed in a mausoleum in the grounds of Charlottenburg, and procured great fame for the artist. The erection of nearly all public statues came to be entrusted to him. There were, among others, Bülow and Scharnhorst at Berlin, Blücher at Breslau, Maximilian at Munich, Francke at Halle, Dürer at Nuremberg, Luther at Wittenberg, and the grand-duke Paul Frederick at Schwerin. At length, in 1830, he began, along with Schinkel the architect, the models for a colossal equestrian monument at Berlin to Frederick the Great. This work was inaugurated with great pomp in May 1851, and is regarded as one of the masterpieces of modern sculpture. Princes decorated Rauch with honours and the academies of Europe enrolled him among their members. A statue of Kant for Königsberg and a statue of Thaeer for Berlin occupied his attention during some of his last years; and he had just finished a model of "Moses praying between Aaron and Hur" when he was attacked by his last illness. He died on the 3rd of December 1857.

RAUCOURT, MILLE (1756–1815), French actress, whose real name was Françoise Marie Antoinette Saucotte, was born in Nancy on the 3rd of March 1756, the daughter of an actor, who took her to Spain, where she played in tragedy at the age of twelve. By 1770 she was back in France at Rouen, and her success as Euphémie in Bellay's Géson et Bayard caused her to be engaged at the Comédie Française where in 1772 she made her début as Dido. She played all the classical tragedy parts to crowded houses, until the scandals of her private life and her extravagance ended her popularity. In 1776 she suddenly disappeared. Part of the ensuing three years she was in prison for debt, but some of the time she spent in the capitals of Northern Europe, followed everywhere by scandal. Under protection of the queen she reappeared at the Théâtre Français in 1779, and renewed her success in Phèdre, as Cleopatra, and all her former rôles. At the outbreak of the Revolution she was imprisoned for six months with other royalist members of the Comédie Française, and she did not reappear upon that stage until the close of 1793, and then only for a short time. She deserted, with a dozen of the best actors in the company, to found a rival colony, but a summons from the Directory brought her back in 1797. Napoleon gave her a pension, and in 1806 she was commissioned to organize and direct a company that was to tour Italy, where, especially in Milan, she was enthusiastically received. She returned to Paris a few months before her death on the 15th of January 1815. Her funeral was the occasion of a riot. The clergy of her parish having refused to receive the body, the crowd broke in the church doors, and were only restrained from further violence by the arrival of an almoner sent post-haste by Louis XVIII. She is buried at Pére Lachaise.

RAUDNITZ (Czech Roudnice nad Labem), a town of Bohemia, Austria, 44 m. N. of Prague by rail. Pop. (1900) 7986, mostly Czech. It is situated on the Elbe, and its chief attraction lies in the interesting and valuable collections in its château, which has belonged to the princely family of Lobkowitz since the beginning of the 17th century. These include a library with a large number of the earliest specimens of printing and valuable MSS., together with a series of pictures from the time of Charles V. to the Thirty Years' War. In 1350 Cola di Rienzi, "the last of the tribunes," was confined by the emperor Charles IV. in the castle, which occupied the site of the present château, previous to his despatched to the pope at Avignon. In 1184 Raudnitz is mentioned as belonging to the see of Prague. The title of duke of Raudnitz was conferred on the head of the family of Lobkowitz by the emperor Joseph II. in 1786.

RAUMER, FRIEDRICH LUDWIG GEORG VON (1781–1873), German historian, was born at Wörthitz in Anhalt on the 14th of May 1781. His father (d. 1822), as Kammerdirektor in Anhalt, did excellent service to agriculture. After studying at the Joachimsthal Gymnasium, Berlin, and at the universities of Halle and Göttingen, Raumer began to practise law, and rose in the civil service under Hardenberg, the chancellor. He was made a professor at the university of Breslau in 1811, and in 1819 he became professor of political science and history at Berlin, holding the chair until 1847, and giving occasional lectures until 1853. In 1815 he had carried on historical investigations in Venice, and in the two following years he had travelled in Germany, Switzerland and Italy. In 1848 he was elected a member of the German parliament at Frankfort, where he associated himself with the right centre, supporting the proposal for a German empire under the supremacy of Prussia; and he was one of the deputation which offered the imperial crown to Frederick William IV. After the breakdown of the German parliament, Raumer returned to Berlin, where he was made a member of the first chamber of the Prussian parliament. He died at Berlin on the 14th of June 1873. Raumer's style is direct, lucid and vigorous, and in his day he was a popular historian, but judged by strictly scientific standards he does not rank among the first men of his time.

His first work, published anonymously in 1806, was entitled Sechs Dialoge über Krieg und Handel. This was followed by Das britische Besteuergungssystem (1810), Handbuch merkwürdiger Stellen aus den lateinischen Geschichtschriften des Mittelalters (1813), Geschichte der deutschen Verhältnisse im 5. und 6. Jahrhundert (1832–36), Geschichte deutscher Völker (1840), and Geschichte deutscher Völker (1840–62). Among his later books may be mentioned Antiquarische Briefe (1851), Reichs- und Staatsverhältnisse der Münzen, Medaillen und Siegel (1860), Lebenserinnerungen und Briefwechsel (1861) and Handbuch der Geschichte der Literatur (1864–66). In 1830 Raumer began the Historisches Taschenbuch published by Brockhaus, which from 1871 was continued by Riehl.
RAVAILLAC—RAVEN

in St. Peterburg. He preached at times in the German Lutheran church, wrote his first tragedies, and in 1817 was appointed professor of German literature and history at a training college in connexion with the university. Owing to an outburst of jealousy against Germans in Russia, culminating in police supervision, Raupach left St. Petersburg in 1822 and undertook a journey to Italy. The literary fruits of his travels were Hirsemens Briefe aus und über Italien (1823). He next visited Weimar, but, being coldly received by Goethe, abandoned his idea of living there and settled in 1824 in Berlin. Here he spent the remainder of his life, writing for the stage, which for twenty years he greatly influenced, if not wholly controlled, in the Prussian capital. He died at Berlin on the 18th of March 1852.

Raupach was a prolific writer of both tragedies and comedies; of the former, Die Fürsten Chawansky (1818), Der Liebe Zauberkreis (1824), Die Leibeigenen, oder Isidor und Olga (1826), Rafelet (1828), Der Nebelungenhort (1834) and Die Schule des Lebens (1841), and of the latter Die Schleichhund (1828) and Der Zeitgeist (1836) are pieces which have enjoyed great popularity, owing to their skillful dramatic handling. On the other hand, the historical dramas with which his name is chiefly associated, Die Hohenstaufen (1837–38), a cyclus of 15 dramatic pieces founded on Friedrich von Raumers Geschichte der Hohenstaufen, as also the trilogy Cromwell (1841–44), are superficial in treatment. Raupach had a great knowledge of theatrical effect and situations, but he contends historical facts in order to suit his political hobby, which was the separation of church and state.

RAVAILLAC, FRANÇOIS (1578–1610), the assassin of Henry IV. of France, was born near Angoulême. He was of humble origin and began life as a valet de chambre, but afterwards became a lawyer and also teacher of a school. After having been imprisoned by his creditors, he sought admission to the recently founded order of Feuillants, but after a short probation was dismissed as a visionary. An application for admission to the Society of Jesus was equally unsuccessful in 1606. His disappointments fostered a fanatical temperament, and rumours that the king was intending to make war upon the pope suggested to him the idea of assassination, which he carried out on the 4th of May 1610. In the course of his trial he was repeatedly put to the torture, but persistently (and it is now believed truly) denied that he had been prompted by any one or had any accomplices. Sentence of death was carried out on the 27th of May following.

RAVAILLON-MOLLEN, JEAN GASPARD FÉLIX (1813–1900), French philosopher and archaeologist, was born at Namur on the 23rd of October 1813. After a successful course of study at the Collège Rollin, he proceeded to Munich, where he attended the lectures of Schelling, and took his degree in philosophy in 1836. In the following year he published the first volume of his famous work Essai sur la métaphysique d’Aristote, to which in 1846 he added a supplementary volume. This work not only criticizes and comments on the theories of Aristotle and the Peripatetics, but also deduces from them a modern philosophical system. In 1838 he received the degree of doctor, and became professor of philosophy at Rennes. From 1840 he was inspector-general of public libraries, and in 1856 became inspector-general in the department of higher education. He was also a member of the Academy, and of the Academy of Moral and Political Science, and curator of the Department of Antiquities at the Louvre (from 1870). He died in Paris on the 28th of May 1900. In philosophy, he was one of the school of Cousin, with whom, however, he was at issue in many important points. The act of consciousness, according to him, is the basis of all knowledge. These acts of consciousness are manifestations of will, which is the motive and creative power of the intellectual life. The idea of God is a cumulative intuition given by all the various faculties of the mind, in its observation of harmony in nature and in man. This theory had considerable influence on speculative philosophy in France during the later years of the 19th century.

Ravaisson’s chief philosophical works are: “Les Fragments philosophiques de Hamilton” (in the Revue des Deux Mondes, November, 1840); Rapport sur le stoïcisme (1831); La Philosophie en France au dix-septième siècle (1868; 3rd ed., 1889); Morale et philosophie (1843). Eminently as a philosopher, Ravaisson was also an archaeologist, and contributed articles on ancient sculpture to the Revue Archéologique and the Mémoires de l’Académie des Inscriptions. In 1871 he published a monograph on the Venus of Milo.

See Renouvier, in L’Année philosophique (Paris, 1868); Dauriac, “Ravaisson philosophe et critique” (La Critique philosophique, 1885, vol. ii.).

RAVANAストロン, an Indian stringed instrument played with a bow, used by wandering pilgrims. A Hindu tradition affirms that the musical bow was invented before 3000 B.C. by Ravanon, king of Ceylon, and that the instrument for which he invented it was named after him Ravanon.1 Judging from precedent, it is probable that the ravaneston of the present day has changed little, if at all, for many centuries. It consists of half a round gourd, over which is fixed a sound-board of skin or parchment; to this primitive body without incurvature is attached a neck about twice the length of the body. The strings are either one or four in number, the pegs being set in the sides of the neck. The bridge is primitive and either straight or slightly arched, so that in bowing more than one string sounds at once.

The ravaneston is regarded by some writers as the first ancestor of the violin, on account of the alleged invention of the bow for use with it. This theory can only be accepted by those who consider the bow, which after all was common to such inferior instruments as the rebeck, as of paramount importance, and the structural features of the instrument itself, the box sound-chest with ribs, which have always belonged to the most artistic types of instruments, such as the cithara and the guitar-fiddle, as of secondary importance. (K. S.)

RAVELLO, a village of Campania, Italy, in the province of Salerno, about 3 m. N.N.E. of Amalfi by road, 1227 ft. above sea-level. It commands a magnificent view. Pop. 1805 1851. The history of Ravello cannot be traced beyond the 9th century. In the 11th it was called Rebelleum, because it refused to acknowledge the sovereignty of Amalfi, and in the 13th, when at the height of its prosperity, it had 36,000 inhabitants. The Palazzo Rufolo, begun in the 11th century, has two lofty towers and beautiful Saracen decoration in the courtyard. The ex-cathedral of S. Pantaleo, almost entirely modernized, has fine bronze doors by Barisianus of Trani (1179), and two pulpits in Cosmatesque work. The larger, supported by six columns resting on the backs of lions, was made in 1272 by Nicolaus of Foglia; the bust over the entrance to it is said to be a portrait of Sigismondo Rufolo. The smaller, of the same date, is simpler, and has curious representations of Jonah and the whale. The parish church of S. Giovanni in Toro, spolia by restorations in the 18th century, contains a splendid pulpit in Cosmatesque work, supported on four pillars, and the crypt some 14th-century frescoes. In front of it is the porch of the Palazzo dell’ Afflito, composed of ancient fragments. S. Maria Immacolata is another Romanesque church.

See A. Avena, Monumenti dell’ Arte Meridionale (Naples, 1902), i. 349 sqq.

RAVEN (O.E. hræfna, Icel. hræfn, Dan. ravn, Du. roaf, Ger. Raben), the largest of the birds of the order Passeres, and a member of the family Corvidae, probably the most highly developed of all birds. Quick-sighted, sagacious and bold, the raven preys on the spoils of fishers and hunters, as also on weakly

1 An illustration appears in Sonnerat’s Voyages aus Indes orientales (Paris, 1806), vol. i. p. 182.
animals among flocks and herds. A sentiment of veneration or superstition has from remote ages and among many races attached itself to the raven. The raven is associated with various characters of history, sacred or profane—Noah and Elijah, Odin and Flinki, the last of whom by its means discovered Iceland. It is said to have played its part in the mythology of the Red Indian; and it has often figured in prose and verse, from the time of Shakespeare to that of Poe and Dickens. Superstition has been generally succeed by persecution, which in many districts has produced extirpation.

The raven breeds very early in the year, in England resorting to its nest, which is usually an ancient if not an ancestral structure, about the middle or towards the end of January. Therein are laid from five to seven eggs of the common Corvina coloration (see Crow), and the young are hatched before the end of February. In more northern counties the breeding season is naturally delayed, but everywhere this species is almost, if not quite, the earliest breeder. The raven's eggs are about 2½ in. in length, and has an expanse of wing considerably exceeding a yard. Its bill and feet are black, and the same may be said of its whole plumage, but the feathers of the upper parts as well as of the breast are glossy, reflecting a bright purple or steel-blue. The species (Corvus corax) inhabits the whole of Europe, and the northern if not the central parts of Asia; but in the latter continent its southern range is not well determined. In America it is, or used to be, found from the shores of the Polar Sea to Guatemala if not to Honduras, but is said hardly to be found of late years in the eastern part of the United States. In Africa its place is taken by three allied but well-differentiated species, two of which (Corvus umburinus, readily distinguished by its brown neck, and C. affinis, having its superior nasal bristles upturned vertically) also occur in south-western Asia, while the third (C. leptonyx or C. tingitanus, a smaller species characterized by several slight differences) inhabits Barbary and the Atlantic Islands. Farther to the southward in the Ethiopian region three more species appear whose plumage is varied with white—C. scapulatus, C. albicollis, and C. crassirostris—the first two of small size, but the last rivaling the real raven in that respect. (A. N.)

RAVEN-HILL, LEONARD (1867— ), English artist and illustrator, was born on the 10th of March 1867. He was educated at Bristol grammar school and the Devon county school, and studied art at Lambeth and then in Paris under MM. Bougeareu and Aimé Morot. He began to exhibit at the Salon in 1887, and in the Royal Academy in 1889. In 1893 he founded, with Arnold Goldworthy, the humorous and artistic monthly The Butterfly (1893–94, revived in 1899–1900). He contributed to many illustrated magazines, and began to work for Punch, with which he was afterwards prominently associated, in 1896. He illustrated Sir Walter Besant's East London (1901) and J. H. Harris's Cornish Saints and Sinners; he published the impressions of his visit to India on the occasion of the tour of the prince and princess of Wales as An Indian Sketch-Book (1903); and his other published sketch-books include Our Battalion (1902) and The Promenaders (1894).

RAVENNA, a city and archiepiscopal see of Emilia, Italy, capital of the province of Ravenna, standing in a marshy plain 13 ft. above sea-level, 6 m. from the sea and 45 m. by rail east of Bologna. Pop. (1906) 35,543 (town), 67,379 (commune)—a considerable increase, as the population was only 35,270 (commune). The industries are few, the growing of wine, breeding of silkworms, making of agricultural instruments, printing and the manufacture of laces being the chief. The town is connected with the sea by the Corsini Canal, the two small rivers Roscel and Mona being connected by means of a communication. Ravenna has railway communication with Bologna (via Castel Bolognese), Ferrara and Rimini, and by steam tram with Forli. At the mouth of the canal is a small harbour.

No other city in the world offers so many and such striking examples of the ecclesiastical architecture of the centuries from the 5th to the 8th. The style is commonly called Byzantine; but some of the most striking features of the churches of Ravenna—the colonnades, the mosaics, perhaps the cupolas—are not so much Byzantine as representative of early Christian art generally. The following are the most important churches of Ravenna, arranged in the order of the dates generally attributed to them:

<table>

(The churches marked A. were originally erected for the Arian worship.)

Almost the only sacred building previous to the 5th century of which we have any record is unfortunately lost. The cathedral of Ravenna, built by S. Ursus in 370–390, which had a nave and four aisles, was destroyed in 1734–44, only the inaccessible crypt and the round campanile remaining from the earlier structure; there are fragments of reliefs from a pulpit erected by Archbishop Agnellus (546–560) in the interior of a rare work on the earlier church (Buonamici, La Metropolitana di Ravenna) gives details of its construction. The present cathedral contains several early Christian marble sarcophagi, a silver cross of the 6th century (that of Agnellus), and the so-called throne of the Archbishop Maximian (546–552), adorned with reliefs in ivory, which, however, was really brought to Ravenna in 1005 by John the Deacon, who recorded the fact in his Venetian chronicle, as a present from the Doge Pietro Orseolo to the Emperor Oto III.

The period from the transference of the imperial residence to Ravenna to the death of Valentinian III. (404–455) was the first period of great building activity in Ravenna, when the archiepiscopal see of Ravenna attained great importance. It was to it that we owe the erection of the Basilica Petriana at Classe (406–425), which has entirely disappeared, of the churches of S. Giovanni Evangelista (425), of S. Agata (425–432), of the chapel of S. Pier Crysologus (432–440), of the tomb of Gallia Placidia (440), the church of S. Pier Maggiore (now S. Francesco) (432–458), the baptistery of Neon (449–458), S. Giovanni Battista and S. Croce.

Rivoira, in the book cited below, shows that many of the characteristic architectural details can be traced back to a classical and in particular a Roman origin, and were not derived from the East, e.g. the use of blind arches as an external decoration, and of brick cornices with the points of the bricks projecting like the teeth of a saw, the use of pulvini (cushions) above the capitals of columns and under the spring of an arch, &c. &c., the use of round arches springing direct from these cushions, spherical pendentives, &c.

Of this group of churches, S. Giovanni Evangelista, erected by Gallia Placidia in fulfilment of a vow made on her voyage from Constantinople, has been entirely rebuilt, though the columns are ancient (the Corinthian capitals are probably from a classical building), and the crypt may be original. The Gothic portal is fine, and the church contains a mosaic pavement of 1213 with curious representations and some frescoes by Giotto, painted during a visit to Dante between 1317 and 1320. S. Agata was almost entirely rebuilt in 1476–94. The
RAVENNA

chapel of S. Pier Crisologo in the archiepiscopal palace preserves its original mosaics, and so also does the tomb of Galla Placidia (SS. Nazario e Celso), a small structure in the form of a Latin cross with a dome (in which, as in the baptistery of Neon, the old cathedral, &c., the constructional use of amphorae is noteworthy), with a plain brick exterior, and rich mosaics on a dark blue ground within. The sarcophagus of Galla Placidia has, like the two others that stand here, been despoiled of its contents. The altar, like that at S. Vitale, is made of thin slabs of alabaster, behind which lamps were intended to be placed.

S. Francesco, as it has been called since 1261, when it came into the possession of the Franciscans, has been almost entirely modernized, except for the crypt and campanile (11th century). The baptistery adjacent to the cathedral was, according to Ricci, originally part of the Roman baths, converted to a Christian baptistery by the Archbishop Neon (449-452), though according to other authorities it is a Christian building, dating from before a.d. 396. It is an octagon, with a dome; in the interior are two arcades one above the other. The mosaics of the 9th century, in the dome, are the earliest and perhaps the finest at Ravenna for their splendid decorative effect and rich colouring, and are less stiff and conventional than the later mosaics.

Of S. Giovanni Battista, also erected in this period, hardly anything remains after the restoration of 1683, and S. Croce has been overtaken by a similar fate.

After the death of Valentinian III, the activity in building for which Ravenna had been so remarkable suffered a check; but the reign of Theodoric (493-526) marks another era of magnificence. In the eastern part of the city he built for himself a large palace, which probably occupied about a sixth of the space now enclosed within the city walls, or nearly the whole of the rectangle enclosed by Strada Porta Alberoni on the south, Strada Nuova di Porta Serrata on the west and the line of the city walls on the north and east. There still remains close to the first-named street and fronting the Corso Garibaldi a high wall built of square Roman bricks, with pillars and arched recesses in the upper portion, which goes by the name of Palazzo di Teodorico. Freeman, on account of the Romanesque character of the architecture, thought it probable that it really belongs to the time of the Lombard kings, and his opinion is shared by Ricci and Rivoira, who consider it to be a guardhouse erected by the exarchs, recent explorations having made it clear that it was an addition to the palace, while mosaic pavements and an atrium once surrounded by arcades really belonging to the latter were found in 1870 behind S. Apollinare Nuovo and in 1908 behind the so-called Palazzo at a lower level and a different orientation. A mosaic in the church of S. Apollinare Nuovo gives some faint idea of the palace. A more memorable and clearly authentic monument of Theodoric is furnished by his tomb, a massive mausoleum which stands still perfect outside the walls near the north-east corner of the city. It is circular internally and decagonal externally, in two storeys, built of marble blocks, and surmounted by an enormous monolith, brought from the quarries of Istria and weighing more than 300 tons. The plan is no doubt derived from that of a Roman tomb. In this mausoleum Theodoric was buried, but his body was cast forth from it, perhaps during the troublous times of the siege of Ravenna by the imperial troops, and the Rotunda (as it is now generally called) was converted into a church dedicated to the Virgin.

S. Apollinare Nuovo, the most important basilica in the town, was built by Theodoric to be the largest of Arian churches, and originally called S. Martino in Coele Auroe (a name which it lost in the 8th century). The exterior is uninteresting, and the church lost both atrium and apse in the 16th century. The interior has twenty-four columns of marble (from Constantinople according to some, from Rome according to others), with almost uniform capitals. The walls of the nave are adorned with mosaics of the 6th century; the scenes from the New Testament above the windows date from the time of Theodoric, while the somewhat stiff processions below, of virgins on one side and of saints on the other, are substitutions of the latter half of the 6th century for representations which probably contained some allusion to Arianism or episodes in the life of Theodoric (so Ricci). The mosaics have been in parts much restored; but the earlier ones still show, like those which preceded them in Ravenna, classical forms, variety of treatment and freedom of colouring, while the processions are monotonous and inferior in execution, intended rather to produce a decorative effect than beauty of form. The pulpit appears to be of Byzantine origin (Rivoira). The campanile (850-878) is circular, and has perhaps the earliest example of the use of disks of coloured majolica as a decoration. This, like the other campanili of Ravenna, is later than the church to which it belongs. Those of the cathedral of S. Apollinare in Classe, S. Maria Maggiore and S. Agata, also circular; probably belong also to the 9th century, while the two square campanili of S. Giovanni Evangelista and S. Francesca probably belong to the early 11th century. The other churches erected by Theodoric are: S. Teodoro (or S. Spirito), erected by Theodoric for the Arian bishops, but entirely modified: the baptistery of this church (afterwards the oratory of S. Maria in Cosmedin) formed out of the octagonal hall of a Roman bath (?); unless it is an originally Christian building—with mosaics of the 6th century imitating those of the baptistery of Neon, and freely restored; S. Maria Maggiore, founded by the Archbishop Ecclesius (521-534), but almost entirely rebuilt; and S. Vitore, which has suffered a similar fate. To the same period probably belong a few columns of the so-called Basilica of Heraclius in the Piazza Vittorio Emanuele, with capitals like those of S. Apollinare in Classe.

The impulse given by Theodoric was continued by his successors, and during the regency of Amalasuntha and the reigns of Theodatus and Vitiges (526-539), S. Vitale and S. Apollinare in Classe were constructed by Julius Argentarius contemporaneously with S. Lorenzo in Milao and the cathedral of Parenzo—also S. Michele in Africisco, nothing of the original structure of which now exists. The former, well restored by Ricci in 1898-1900 (except for the dome with its baroque frescoes which has not been altered), is a regular octagon, with a vestiule, originally flanked by two towers on the west, a choir added on the east, triangular outside and circular within; it is surrounded within by two galleries interrupted at the presbytery, and supported by eight large pillars, the intervals between which are occupied by open exedrae. The mosaics of the choir (547) are due to Justinian, and, though inferior in style, are remarkable for their splendour of colouring and the gorgeous dresses of the persons represented, and also for their historical interest, especially the scenes representing the emperor and the empress Theodora presenting offerings. The marble screens of the altar are wonderfully finely carved. The marble mosaic pavement (11th century) is very effective. Remains of the original marble wall lining and stucco decoration also exist. The capitals are, in the lower order, the characteristic funnel-shaped rectangular Byzantine capitals, some of them with open work, bearing cushions; this is a type probably derived from the cushion itself, and developed in the East about the second half of the 5th century.

The architecture of S. Vitale (for plan see Architecture, sect. Early Christian), according to Rivoira, was inspired not by Byzantium, where similar churches—S. Sofia and SS. Sergio and Bacco—are slightly later in date, but by the churches of Salonica (A.D. 405), while the plan is derived from a Christian baptistery, or from such a building as the so-called temple of Minerva Medica at Rome.

S. Apollinare in Classe, erected at the same time outside the walls of Classe, and now standing by itself in the lonely marshes, is the largest basilica existing at Ravenna. It has a nave and aisles with a closed vestibule on the west, and a fine round campanile of the 9th (? century). The exterior brick walls are divided by shallow arches and pilasters, as in other churches of Ravenna. It has twenty-four columns of Carystian (cipollino) marble, with capitals probably of Byzantine work with swelling...
Ravenna. "It is the largest of all the cities built in the lagoons, but entirely composed of wooden houses, penetrated in all directions by canals, wherefore bridges and boats are needed for the wayfarer. At the flow of the tide a large part of the sea comes sweeping into it; and thus, while all the muddy deposit of the rivers is swept away, the malaria is at the same time removed, and by this means the city enjoys so good a sanitary reputation that the government has fixed on it as a place for the reception and training of gladiators." On the other hand, good water was proverbially difficult to obtain at Ravenna—dearer than wine, says Martial, who has two epigrams on the subject. Trajan, however, built an aqueduct nearly 20 miles long, which was restored by Theodoric in 503. Of this some traces still exist in the bed of the Ronco above Ravenna. Flies and frogs were also complained of, and Sidonius, writing in the 5th century, complains bitterly of the "feculent gruel" (cloacæ puls) which filled the canals of the city, and gave forth fetid odours when stirred by the poles of the bargemen. The port of Ravenna, situated about 3 miles from the city, was named Classis. A long line of houses called Caesarea connected it with Ravenna, and in process of time there was such a concentration of buildings that the three towns thus united were called one. It was a municipium under the Empire, as the inscriptions show, but it seems to have had magistrates rather suited to a vicus or village, its importance being due entirely to the naval station (cf. the state of things at Mediolanum, Milan). It had large gilds of fabri (smiths and carpenters) and centonarii (firemen).

Of Roman Ravenna nothing remains above ground, though a little has been found by excavation, including a mosaic pavement at Classe near S. Severo (Ricci, op. cit. p. 50). Among the tombs many of the poorer under the Empire were simply formed of amphorae, in which the body was placed. A prehistoric station was found in 1894 at S. Zaccaria near Ravenna, belonging to a Terramare (E. Brizio in Notizie degli Scavi, 1896, 85). In A.D. 330 it is spoken of as having previously been the chief town of Picenum, but having recently been assigned to Aemilia. It was connected with Ariminum, 33 miles to the south by the coast road, the Via Popilia, which ran on north to Hatra, and joined the road between Patavium and Altinum (end of 2nd c. B.C.)

The great historical importance of Ravenna begins early in the 5th century, when Honorius, alarmed by the progress of Alaric in the north of Italy, transferred his court hither. From this date (404) to the fall of the Western Empire in 476 Ravenna was the chief residence of the Roman emperors. Here Stilicho was slain; here Honorius and his sister Placidia caressed and quarrelled; here Valentinian III. spent the greater part of his life; here Majorian was proclaimed; here the little Romulus donned his purple robe; here in the pinewood outside the city his uncle Paulus received his decisive defeat from Odoacer.

Through all these changes Ravenna maintained its character as an impregnable "city in the sea," not easily to be attacked even by a naval power on account of the shallowness and devious nature of the channels by which it had to be approached. Odoacer, like the emperors who had gone before him, made Ravenna his chief place of residence, and here he shut himself up when Theodoric the Ostrogoth had invaded Italy and defeated him in two battles. Theodoric's siege of Ravenna lasted for three years (490-492), and was marked by one bloody encounter in the pinewood on the east of it. The Ostrogoths collected a fleet and established a severe blockade, which at length caused Odoacer to surrender the city. The terms, arranged through the intervention of John, archbishop of Ravenna, were not observed by

The great pinewood to the east of the city, which is still one of the great glories of Ravenna, must have been in existence already in the 5th century. Byron's description,

"[The] immemorial wood
Rooted where once the Adrian wave flowed o'er;"

is probably true; but there is no evidence that it was in historic time that this change took place. It may be conjectured that the pineta grew on a large peninsula somewhat resembling the Lido of Venice.

antarbus leaves; but the rest of the church is due to native architects. The lofty presbytery and the crypt under it belong to the 12th century. The walls of the interior were stripped of their marble panelling by Sigismundo Malatesta in 1440, for the adornment of his church at Rimini. The apse has mosaics of the 6th and 7th centuries. The 18th-century series of portraits of the archbishops of Ravenna is no doubt copied from an earlier original. There are a number of fine carved sarcophagi in the church (5th to 8th century). The building activity of the Gothic kings was continued by Justinian, to whose time we owe the completion of S. Vitale and S. Apollinare in Classe, and some of the mosaics in S. Apollinare Nuovo.

The buildings of a subsequent period are of minor importance, but the basilica of S. Maria in Porto near the ancient harbour (1096 sq.), a basilica with open roof, with frescoes by masters of the Rimini school, may be noticed. The massive concrete substructures of the campanile are attributed to an old lighthouse. The tomb of Dante, who died at Ravenna in 1321, is close to S. Francesco; it is a square-domed structure, decorated by Pietro Lombardo (1482) representing the poet, and a sarcophagus below, in an urn within which lie the poet's remains, a small court with early Christian sarcophagi, containing the remains of the Bracciolini family. The secularized monastery of Classe, in the town, built by the monks of S. Apollinare in Classe in 1559, as a refuge from the malaria, which prevailed at Classe itself, with fine 17th-century cloisters, contains the important museum, which has Roman and Byzantine antiquities, inscriptions, sculptures, jewelry, &c.—including the possible remains of a suit of gold armour of Theodoric—and a collection of Italian woodcuts; also the library with rare MSS. and incunabula (among the former the best extant MS. of Aristophanes). The Accademia, close by, has a few pictures by local masters, e.g. N. Rondinelli (end of 15th century), of no great importance, and a fine recumbent statue of Guidarello Guidarelli, a condottiero of Ravenna, and a partisan of Caesar Borgia (d. 1507), by Tullio Lombardo (?) or Severo da Ravenna (?)

The Piazza Vittorio Emanuele are two granite columns erected by the Venetians, in 1483, with statues of SS. Apollinaris and Vitalis. The cloisters of S. Maria di Porto erected in the town in the 14th century (out of marble as in the case of the church of Classe), and of S. Vitale, are pleasing 16th-century structures. The 15th-century castle in the north-east corner of the town erected by the Venetians is a picturesque brick building. The famous pineta or pinewood of Ravenna, which already existed in Odoacer's time, and has been sung by poets since Dante, lies some 5 m. south of Ravenna.

History.—Strabo mentions a tradition that Ravenna was founded by Thessalians, who afterwards, finding themselves pressed by the Etruscans, called in their Umbrian neighbours and eventually departed, leaving the city to their allies. Pliny, on the other hand, calls it Sabine. Throughout the valley of the Po the Gauls took the place of the Etruscans as a conquering power; but Ravenna may possibly have retained its Umbrian character until, about the year 127 B.C., by the conquest of the Boii, the whole of this region passed definitely under the dominion of Rome. Either as a colony or a municipium, Ravenna remained for more than two centuries an inconsiderable city of Gallia Cisalpina, chiefly noticeable as the place in which Caesar during his ten years' command in Gaul frequently resorted in order to confer with his friends from Rome, and from which he started for his advance into Italy. At length under Augustus it suddenly rose into importance, when that emperor selected it as the station for his fleet on "the upper sea." Two hundred and fifty ships, said Dion (in a lost passage quoted by Jordanes), could ride at anchor in its harbour. At the same time Augustus conducted a branch of the Po (the fossa Augusta) through the city into the sea. It also became important for the export of timber from the Alps. Strabo, writing probably a few years after Ravenna had been thus selected as a naval arsenal, gives us a description of its appearance which certainly corresponds more closely with modern Venice than with modern
RAVENNA

Theodoric, who, ten days after his entry into the city, slew his rival at a banquet in the palace of the Laurel Grove (March 15, 493). Ravenna was Theodoric's chief place of residence, and his reign (493-526) may be considered the time of its greatest splendour.

Nine years after the death of Theodoric Justinian sent an army to destroy the Gothic monarchy and restore Italy to the empire. Long after the Goths had lost Rome they still clung to Ravenna, till at length, weary of the feehlessness of their own king, Vitiges, and struck with admiration of their heroic conqueror, they offered to transfer their allegiance to Belisarius on condition of his assuming the diadem of the Western Empire. Belisarius dallyed with the proposal until he had obtained an entrance within the walls of the capital, and proclaimed his inviolable fidelity to Justinian. Thus in the year 539 was Ravenna re-united to the Roman empire. Its connexion with that empire—or, in other words, its dependence upon Constantinople—lasted for more than 200 years, during which period, under the rule of Narses and his successors the exarchs, Ravenna was the seat of Byzantine dominion in Italy. In 728 the Lombard king Luitprand took and destroyed the suburb Classe; about 752 the city itself fell into the hands of his successor Astulf, from whom a few years after it was wrested by Fippin, king of the Franks. By this time the alteration of the coast-line and the filling up of the lagoons had probably commenced, and no historical importance attaches to its subsequent fortunes. It formed part of the Frankish king's donation to the pope in the middle of the 8th century, though the archbishops, as a fact, retained almost independent power. It was an independent republic, generally taking the Guelf side in the 13th century, subject to rulers of the house of Polentani in the 14th, Venetian in the 15th (1441), and papal again in the 16th,—Pope Julius II. having succeeded in wresting it from the hands of the Venetians. St Romuald and St Peter Damian were both natives of Ravenna. From this time (1509) down to our own days, except for the interruptions caused by the wars of the French Revolution, Ravenna—continued subject to the papal see and was governed by a cardinal legate. In 1849 Garibaldi's wife Anita, who had accompanied him on his retreat from Rome, succumbed to fatigue in the marshes near Ravenna. In 1859 it was one of the first cities to give its vote in favour of Italian unity, and it has since then formed a part of the kingdom of Italy.

Charles the Great carried off the brazen statue of Theodoric and the marble columns of his palace to his own palace at Aix-la-Chapelle. More than five centuries later (1320) Dante became the guest of Guido Novello di Polenta, lord of Ravenna, and here he died on the 24th September of the following year. The marble urn containing the head of the poet still rests at Ravenna, where by Byron calls "a little cupola more neat than solemn" has been erected over it. In 1512 (see below) the French army under Gaston de Foix fought a fierce battle with the Spanish, Venetian, and papal troops on the banks of the river. The French were victorious, but Gaston fell in the act of pursuing the enemy. His death is commemorated by the Colonna dei Francesi erected on the spot where he fell. Lord Byron resided at Ravenna for eighteen months in 1820-21, attracted by the charms of the Countess Guiccioli.

AUTHORITIES.—The most important authority for the history of Ravenna is Bishop Agnellus, who wrote, about 840, the Liber Pontificum Ecclesiae Ravennatis. The best edition is that by Prof. Eggler in the Monumenta Germaniae Historica (1878). See also E. Bormann, in Corpus Inscription. Latin. xi. (Berlin, 1888), p. 1 sqq.; G. T. Rivoira, Origini dell' Architettura Lombarda, i. (Rome, 1901); C. Ricci, Ravenna (Bergamo, 1902). To the careful restorations of the last named the buildings of Ravenna owe much. (T. H. T. A.)

Battle of 1512.—This battle, one of the principal events of the long Italian war of Charles VIII., Louis XII., and Francis I. of France, like Marignano, became of importance in a tactical sense, from the fact that the feudalism of the past and the expert soldiership of the future were strangely mingled. It arose out of the attempt of the Spanish and Italian forces to relieve Ravenna, besieged by Gaston de Foix, duke of Nemours. The most celebrated captains of these wars were present on either side—under Gaston de Foix were Bayard, Yves d'Allegre, La Palisse; and under Cardona the Spanish viceroy of Naples, Pedro Navarro the great engineer, and Pescara the originator of the Spanish tactical system. After some preliminary manoeuvres the two armies drew up face to face on the left bank of the Roneo, the Spanish left and the French right resting on this river. The Spaniards were entrenched, with their heavy artillery distributed along the front, but, thanks to Navarro, they had a more mobile artillery in the shape of 200 arquebuses à croc mounted in groups upon carts, after the German fashion, and this was held ready to move wherever its services might be needed. The left wing was composed of the papal contingent, 6000 infantry and 800 gendarmes under Fabrizio Colonna; the centre, of half the Spanish contingent, 4000 infantry and 600 lancers under the viceroy; the right, of 1000 light horse under Pescara. Behind the centre was the rest of the Spanish contingent, 600 lancers and 4000 infantry. On the other side the right wing was commanded by the duke of Ferrara, who had liked Navarro organized a mobile field artillery (the artillery material of this prince was thought to be the best conditioned in Europe). It consisted besides of 800 French gendarmes under Louis de Brézé and 5000 German landsknechts under Jakob Empser. In the centre were 8000 French infantry (the ancestors of the later Picardie and Piedmont regiments) under the seigneur de Molart, and 5000 Italian infantry. On the left were the light horse. A reserve of 600 gendarmes under La Palisse was behind the centre. The battle opened with a prolonged cannonade from the Spanish lines. For three hours the professional regiments of all sorts in the French lines ralled one another in enduring the fire unmoved, the forerunners of the military systems of to-day, landsknechts, Picardie and Piedmont, showing the feudal gendarme that they too were men of honour. They remained no lying down. The captains placed themselves in the front, and in the centre 38 out of 40 of them were struck down. Molart and Empser, drinking each other's health in the midst of the cannonade, were killed by the same shot. Sheltered behind the entrenchments, the Spaniards scarcely suffered, for they were lithe active troops accustomed to lie down and spring up from the ground. But after three hours, Pescara's light horse having meantime been driven in by the superior light horse of the enemy, the artillery-loving duke of Ferrara conceived the brilliant plan of taking his mobile field-guns to the extreme right of the enemy. This he did, and so came in sight of the prone masses of the Spaniards. Disciplined troops as they were, they resisted the temptation to escape Ferrara's fire by breaking out to the front; but the whole Spanish line was enflamed, and on the left of it the papal troops, who were by no means of the same quality, filled up the ditch in front of their breastworks and charged forward, followed by all the gendarme. Once in the plain they were charged by the French gendarmes under Gaston himself, as well as by the landsknechts, and driven back. The advantage of position being thus lost, the Spanish infantry rose and flung itself on the attackers; the landsknechts and the French bands were disordered by the fury of the counterstroke, being unaccustomed to deal with the swift, leaping, and crouching attack of swordsmen with bucklers. But La Palisse's reserve wheeled in upon the rear of the Spaniards, and they retreated to the entrenchments as fast as they had advanced. The papal infantry, the gendarmes, and the light horse had already vanished from the field in disorder; but the Spanish regulars were of different mettle, and it was only after a long struggle that the landsknechts and the French bands broke into the entrenchments. A column of landsknechts, Fabian by name, holding his long lance crosswise, brought it down with all his force upon the opposing spears, and at the cost of his life made a narrow gap through which the French broke into the mass of the enemy. Still the conflict continued, but at last La Palisse, with all the gendarme still in hand, rode completely round the entrenchments and charged the Spaniards' rear again. This was the
RAVENNA, EXARCHATE OF—RAVENCROFT

end, but the remnant of the Spanish infantry retreated in order along the river causeway keeping the pursuers at bay with their arquebuses. Gaston de Foix, recklessly charging into the midst of them, was killed.

RAVENNA, EXARCHATE OF, the official name of that part of Italy which remained in the allegiance of the Roman emperors at Constantinople from the closing years of the 6th to the middle of the 8th century. The civil and military head of these possessions, the exarch (pap.), was stationed at Ravenna. The territory round the town, from the southern border of the modern Venetia to the beginning of the Pentapolis at Rimini, was under his direct administration and formed in a limited sense the exarchate. Other provinces were governed by dukes and magistri militium, titles which were generally, but not always, borne by the same person. But as all were subject to his authority, they were included in the exarchate of Ravenna, which was therefore another name for the province of Italy. The borders of these dominions varied according to the fortunes of the imperial authority in its long struggle with the Lombards. Sicily formed a separate government. Corsica and Sardinia belonged to the exarchate of Africa. The exarch of Italy was forced to recognize the exarchate of Beneventum, which began in 568, and their permanent settlement. The Lombards thrust a wedge into Italy. Its base was in Venetia, and its point was advanced to the Tiber. From the early days of the conquest they spread to the south, and established the duchies of Spoleto and Beneventum in the modern kingdom of Naples. They may thus be said to have hollowed out the imperial, or Byzantine, possessions in Italy, the interior being under their power, and the coast remaining to the imperial officers. This illustration, however, is subject to two serious exceptions. As the Lombards spread they came into possession of many parts of the coast. Then a belt of imperial territory stretching from Rimini on the Adriatic, S.W. to the mouth of the Tiber, and including the duchies of Perugia and Rome, served to unite the immediate territory of Ravenna with the duchy of Naples, and to separate the two bodies under Lombard dominion, the kingdom in the north, and the southern duchies Spoleto and Beneventum. The organization of the exarchate is placed by the emperor, Maurice (582–602), when the imperial government began to recognize the necessity of providing for a new and a long struggle. At the end of the 6th century the exarchate included Istria; the maritime part of Venetia as distinct from the interior which was in the hands of the Lombard kings at Pavia; the exarchate proper, or territory around Ravenna on the eastern side of the Appennines, to which was added Calabria, which at that period meant the heel and not the toe of the boot; the Pentapolis, or coast from Rimini to Ancona with the interior as far as the mountains; the duchy of Rome, or belt of territory connecting the Pentapolis with the western coast, the coast of Naples, with Bruttium the toe of the boot; the modern Calabria, and Liguria, or the Riviera of Genoa. The Piedmont, Lombardy, mainland of Venetia, Tuscany and the interior of Naples belonged to the Lombards. The advance of these barbarians was for a time checked during the anarchy which followed the death of Alboin, and the exarchate was able to enjoy complete rule. The superior organization of the imperial government enabled it to regain lost territory and delay complete ruin. In 590 the empire regained much of Venetia. But these revivals were not permanent. The superiority of the empire was a mechanical one, and during the two centuries or so that the exarchate lasted it lost ground. In 640 the Ligurian seacoast fell under the power of the Lombards, and ceased to be an imperial province. About a century later the exarchate had been greatly reduced, though the imperial officials endeavoured to conceal the fact by retaining and transferring names when the reality of possession was lost. About 740 it consisted of Istria, Venetia (the maritime portion of which was being to a province and was becoming a protected state, the forerunner of the future republic of Venice), Ferrara, Ravenna (the exarchate in the limited sense), Pentapolis, Perusia, Rome, the coast of Naples and Calabria (in the sense of the toe and not the heel of the boot) which was being overrun by the Lombards of the duchy of Beneventum, which with Spoleto held the interior. In Rome the pope was the real master. These fragments of the "province of Italy," as it was when reconquered by Justinian, were almost all lost either to the Lombards, who finally conquered Ravenna itself about 750, or by the revolt of the pope, who separated from the empire on account of the iconoclastic reforms. The intervention of Pippin the Caroleingian, who was called in by the popes to protect them against the Lombards and the Eastern emperors alike, made a revival of the exarchate impossible. It disappeared, and the small remnants of the imperial possessions on the mainland, Naples and Calabria, passed under the authority of the "patriarcus" of Sicily, and when Sicily was conquered by the Arabs in the 10th century were erected into the themes of Calabria and Langobardia. Istria was attached to Dalmatia.

In its internal history the exarchate was subject to the influences which were everywhere, in central and western Europe, the reaction from the Carolingian revival and the establishment of feudalism. Step by step, and in spite of the efforts of the emperors at Constantinople, the great imperial officials became landowners, the owners of land—kingsmen or at least associates of these officials—intruded on the imperial administration, while the necessity for providing for the defence of the imperial territories against the Lombards led to the formation of local militias, who at first were attached to the imperial regiments, but gradually became independent. These armed men formed the exercitus romanae militiae, who were the forerunners of the free armed burghers of the Italian cities of the middle ages. The exercitus of Rome was divided into scholae, and had a chief or patronus, and its banner. Other cities of the exarchate were organized on the same model. Diehl is of opinion that the exercitus was formed of the ancient "possessors," or landowners and free townsmen, who were of a less rank than the ordina senatorius. The great landowners who were developing into feudal lords, and the smaller freemen who were becoming independent burghers, broke the imperial connection to towns, and prepared the way for the final ruin of the exarchate.

RAVENSBURG, a town of Germany, in the kingdom of Württemberg, pleasantly situated amid vine-clad hills on the river Schussen, 12 miles S. of Friedrichshafen, on the lake of Constance, by the railway of Ulm. Pop. (1905) 14,014, the great majority of whom are Roman Catholics. Its aspect is medieval; it still retains its walls and nine picturesque towers, the most prominent of which, dating from the 15th century, is known as the "Melshack," or sack of flour. The town hall is a handsome 14th-century building. The manufactures include linen, cotton, embroidered muslins, pottery, glass and playing-cards. The fruit market is important, and there is trade in cattle, grain and timber. Ravensburg was founded in the 11th century by the Guelphs, and in their ancestral castle on the Veitsburg, which was partially restored in 1802, the Saxon duke, Henry the Lion, was born. In 1180 the town passed to the Hohenstaufens, and a century later it became a free town of the Empire. In the 15th century it was a flourishing commercial place, its chief industry being the manufacture of paper. Annexed to Bavaria from 1803 to 1810, it was ceded to Württemberg in the latter year.

See Halner, Geschichte von Ravensburg (Ravensburg, 1887).

RAVENCROFT, Edward (fl. 1671–1697), English dramatist, belonged to an ancient Flintshire family. He was entered at the Middle Temple, but devoted his attention mainly to literature. Among his pieces are Mamamouchi, or The Citizen turned Gentleman (Dorset Garden, 1671, pr. 1675); The Careless Lovers (Dorset Garden, 1673, pr. 1673), a comedy.
of intrigue; Scaramouch a Philosopher, Harlequin a Schoolboy, Bravo a Merchant and Magician (Theatre Royal, 1677); English Lawyer (Theatre Royal, 1678), an adaptation of George Ruggles’s Latin play of Ignoramus, presented before James I. at Cambridge in March 1615; The London Cuckold (Dorset Garden, 1683), which became a stock pæce, but was struck out of the repertory by Garrick in 1751; and The Italian Husband (Lincoln’s Inn Fields, 1697). He wrote in all twelve plays, in which he adapted freely from Molière and others, confessing on one occasion that he “but winnowed Shakespeare’s corn.” He ventured to decry the heroic drama, and Dryden retaliated by satirizing his Mamamouchi, a foolish adaptation from Molière’s Bourgeois Gentilhomme and Monsieur de Pourcagon, in the prologue to the Aisignation (Dryden, Works, ed. Scott, iv. 345 seq.).

RAVI, a river of India, one of the “Five Rivers” of the Punjab. It rises in the Kulu subdivision of Kangra district, flows through Chamba state, and enters British territory again in Gurdaspur district. At Madhpur the head works of the Bari Doab canal draw off a large portion of its waters. Thence it flows through the plains of the Punjab, passing within a mile of Lahore, and finally falls into the Chenab after a course of about 450 miles.

RAVINE, a deep, narrow gorge, cleft or valley in a mountain, worn by the violent rush of water, whence the name, which comes through Fr. from Lat. râpina, violent robbery or plunder (râpere, to seize). The doublet “ravín” or “raven,” robbery, greed, has given place to the more learned form “rapine,” but is still seen in “ravenous,” greedy, voracious.

RAWALPINDI, a town of British India, which gives its name to a district and a division in the Punjab. The town is situated on the north bank of the little river Leh, 1726 ft. above the sea, 111 m. E. by S. of Peshawar, and 1443 m. N.W. of Calcutta. Pop. (1901) 87,688. It is chiefly notable as the largest military station in India, and the key to the British system of defence upon the North-West Frontier. Railways radiate to Peshawar, Kohat, and the Malakand Pass, and a road runs to the Abbotabad frontier. It is also the startingpoint of the cart-road to the hill-station of Murree and of the route into Kashmir. It is protected by a strong chain of forts, commanded by the rawal. It is the headquarters of the second division of the northern army with a strong force of all arms, and contains an arsenal. Besides the locomotive works of the North-Western railway, there are gas-works, a tent factory, an iron foundry, and a brewery. An annual horse fair is held in April.

The District of Rawalpindi has an area of 2010 sq. m., Attok having been separated from it and formed into a separate district in 1904. It is situated on the southern slopes of the north-western extremities of the Himalayas, including large mountain tracts with rich valleys traversed by mountain torrents. It contains the Murree hills with the sanatorium of that name, the chief hill-station in the Punjab. The Indus and the Jhelum are the chief rivers, and the climate is noted for its healthiness. The principal crops are wheat, barley, maize, millets, and pulses. The district is traversed by the main line of the North-Western railway, crossing the Indus at Attok, and also by a branch towards the Indus at Khusalgar. The population in 1901 was 538,699, showing an increase of 47.2% in the decade.

The Division of Rawalpindi lies in the north-west of the Punjab. It consists of the five districts of Gujrat, Attok, Shahpur, Jhelum, and Rawalpindi. The total area is 15,736 sq. m. and the population in 1901 was 2,790,360.

RÄWENDIS, a Persian sect that took its name from a town Rawend near Isfahan. Its origin is unknown, but they held ultra-Shiite doctrines (see Shiites). Under the year 158 (A.D. 775) Tabari says that a man of the Räwendis, called al-Ablaq (because he was leprous), asserted that the spirit that was in Jesus was in 'Ali, then in the imåms one after the other to Ibrahim ibn Mahommed, and that these were gods. Asad ibn 'Abdallah, then governor of Khorasan, put many of them to death. Under the year 135 (A.D. 752-3) the historian again mentions a rising of the Räwendis of Talaqän, and its suppression. Under 141 (A.D. 758-9) he gives a fuller account of them. They believed in metempsychosis, or the transmigration of souls, and asserted that the spirit of Adam was in Othman ibn 'Nâhir, that the Lord who fed them and gave them drink was Abu Ja’far ul-Mansûr, and that al-Haitham ibn Maowiyâ was Gabriel. Accordingly they came to the palace of Mansûr in Hashimiya and began to hail him as Lord. Mansûr, however, secured their chiefs and threw them into prison. By means of a mock funeral they succeeded in reaching the prison and delivering their leaders. They then turned in wrath against Mansûr and almost succeeded in capturing him, but were defeated and slain by al-Haitham.

RAWITSCH (Polish Rawicz), a town of Germany, in the Prussian province of Posen, lying near the Silesian frontier, 37 m. N. of Breslau, at the junction of railways to Posen and Liegnitz. Pop. (1900) 11,403. It contains a handsome Protestant church and a medieval town hall. The principal industry is the manufacture of snuff and cigars, and for the former it enjoys a considerable reputation. Trade is carried on in grain, wool, flax, hides, and timber. Rawicz was founded by Protestant refugees from Silesia during the Thirty Years’ War. It passed to Prussia at the second partition of Poland in 1793.

RAWLINSON, GEORGE (1812-1902), English scholar and historian, was born at Chadlington, Oxfordshire, on the 23rd November 1812, being the younger brother of Sir Henry Rawlinson (q.v.). Having taken his degree at Oxford (from Trinity College) in 1838, he was elected to a fellowship at Exeter College in 1840, of which from 1842 to 1846 he was fellow and tutor. He was ordained in 1841; was Buckmaster lecturer in 1859, and Camden professor of ancient history from 1861 to 1889. In 1872 he was appointed canon of Canterbury, and after 1888 he was rector of All Hallows, Lombard Street. In 1873 he was appointed proctor in Convocation for the Chapter of Canterbury. He married Louisa, daughter of Sir R. A. Chermside, in 1846. His chief publications are his translation of the History of Herodotus (in collaboration with Sir Henry Rawlinson and Sir Gardner Wilkinson), 1859-60; The Five Great Monarchies of the Ancient World, 1867; The Sixth Great Oriental Monarchy (Parthian), 1873; The Seventh Great Oriental Monarchy (Sassanian), 1875; Manual of Ancient History, 1869; Historical Illustrations of the Old Testament, 1871; The Origin of Nations, 1877; History of Ancient Egypt, 1881; Egypt and Babylon, 1885; History of Phœnicia, 1889; Parthia, 1893; Memoir of Major-General Sir H. C. Rawlinson, 1898. He was a contributor to the Speaker’s Commentary, the Pulpit Commentary, Smith’s Dictionary of the Bible, and various similar publications; and he was the author of the article “Herodotus” in the 9th edition of the Encyc. Brit. He died on the 7th of October 1902.

RAWLINSON, SIR HENRY CRESWICKE (1812-1895), English soldier and orientalist, was born at Chadlington, Oxfordshire, on the 11th of April 1810. In 1827 he went to India as cadet under the East India Company; and after six years’ life with his regiment as subaltern, during which time he had become proficient in the Persian language, he was sent to Persia with some other English officers to drill and reorganize the Shah’s troops. It was at this time that he was first attracted to the study of inscriptions, more particularly those in the hitherto undeciphered cuneiform character. In the course of the two years during which he was in its immediate neighbourhood he transcribed as much as he was able of the great cuneiform inscription at Behistun (q.v.); but the friction between the Persian court and the British government ended in the departure of the British officers.

He was appointed political agent at Kundahar in 1840. In that capacity he served for three years, his political labours being as meritorious as was his gallantry during various engagements in the course of the Afghan War; for these he was rewarded by the distinction of C.B. in 1844. A fortunate chance, by which
RAWLINSON, R.—RAWMARSH

RAWLINSON, R.—RAWMARSH

he became personally known to the governor-general, led to his being appointed, at his own desire, as political agent in Turkish Arabia; thus he was enabled to settle in Bagdad, where he devoted much time to the cuneiform studies which attracted him. He was now able, under considerable difficulties and with no small personal risk, to make a complete transcript of the Behistun inscription, which he was also successful in deciphering and interpreting. Having collected a large amount of invaluable information on this and kindred topics, in addition to much geographical knowledge gained in the prosecution of various explorations (including visits with Layard to the ruins of Nineveh), he returned to England on leave of absence in 1849. He remained at home for two years, published in 1851 his memoir on the Behistun inscription, and was promoted to the rank of lieutenant-colonel. He disposed of his valuable collection of Babylonian, Sabean, and Sassanian antiquities to the trustees of the British Museum, who also made him a considerable grant to enable him to carry on the Assyrian and Babylonian excavations initiated by Layard. In 1851 he returned to Baghdad. The excavations were carried on under his direction with valuable results, among the most important being the discovery of material that greatly contributed to the final decipherment and interpretation of the cuneiform character. An accident with which he met in 1855 hastened his determination to return to England, and in that year he resigned his post in the East India Company. On his return to England the distinction of K.C.B. was conferred upon him, and he was appointed a crown director of the East India Company. The remaining forty years of his life were full of activity—political, diplomatic, and scientific—and were mainly spent in London. In 1858 he was appointed a member of the first India Council, but resigned in 1859 on being sent to Persia as envoy extraordinary and minister plenipotentiary. The latter post he held only for a year, owing to his dissatisfaction with circumstances connected with his official position there. Previously he had sat in Parliament as M.P. for Reigate from February to September 1858; he sat again as M.P. for Frome, 1865–68. He was appointed to the Council of India again in 1868, and continued to serve upon it until his death. He was a strong advocate of the forward policy in Afghanistan, and counselled the retention of Kandahar. His views were more particularly expressed in England and Russia in the East, 1875. He was a trustee of the British Museum from 1876 till his death. He was created G.C.B. in 1889, and a Baronet in 1891; was president of the Geographical Society from 1874 to 1875, and of the Asiatic Society from 1875 to 1881; and received honorary degrees at Oxford, Cambridge, and Edinburgh. He married, in September 1862, Louisa Caroline Harcourt; they had two sons and died in 1889. He died in London on the 5th of March 1893. His published works include (apart from minor contributions to the publications of learned societies) four volumes of cuneiform inscriptions, published under his direction between 1870 and 1884 by the trustees of the British Museum; The Persian Cuneiform Inscription at Behistun, 1846–51, and Outline of the History of Assyria, 1852, both reprinted from the Asiatic Society's journals; A Commentary on the Cuneiform Inscriptons of Babylon and Assyria, 1859; Notes on the Early History of Babylonia, 1854; England and Russia in the East, 1875. He contributed to the Encyclopaedia Britannica (9th edition) the articles on Bagdad, the Euphrates and Kurdistan, and several other articles dealing with the East; and assisted in editing a translation of Herodotus by his brother, Canon George Rawlinson. See C. H. Lamartine, Memoir of Henry Creswicke Rawlinson (1898).

RAWLINSON, RICHARD (1660–1755). English antiquary and divine, was a younger son of Sir Thomas Rawlinson (1647–1708), lord mayor of London in 1705–6, and a brother of Thomas Rawlinson (1681–1725), the bibliophile. Born on the 3rd of January 1660, he was educated at St Paul’s school, at Eton, and at St John’s College, Oxford. In 1716 he was ordained, but as he was a nonjuror and Jacobite the ceremony was performed by a nonjuring bishop, Jeremy Collier. Rawlinson then travelled in England and on the continent of Europe, where he passed several years, making collections of manuscripts, coins and curiosities. In 1728 he became a bishop among the nonjurors, but he hardly ever appears to have discharged episcopal functions, preferring to pass his time in collecting books and manuscripts, pictures and curiosities. He died at Islington on the 6th of April 1755. Rawlinson left his manuscripts, his curiosities, and some other property to the Bodleian Library; he endowed a professorship of Anglo-Saxon at Oxford, and was a benefactor to St John's College.
in 1830 with the exception of the Norman tower. Rawmarsh has large iron-works, steel rolling-mills and potteries, and there are collieries in the neighbourhood. At the time of the Conquest the manor was granted to Walter d'Eyncourt, and in the 12th century it was divided among the three daughters of his tenant Ralph Paganel, who is supposed to have been the founder of the church.

RAWTENSTALL, a municipal borough in the Rossendale parliamentary division of Lancashire, England, 17° 3′ N. by W. from Manchester by the Lancashire & Yorkshire railway. Pop. (1901) 31,053. This town is a modern creation of the cotton industry; at the beginning of the 19th century it was a secluded village in the wild hilly district of Rossendale Forest. The cotton and woollen industries employ the majority of the inhabitants, and there are stone quarries in the neighbourhood. The town was incorporated in 1891, and the corporation consists of a mayor, 6 aldermen and 18 councillors. Area, 9,535 acres.

RAY (Lat. raia). The rays (Batoidei) together with the sharks (Selachioidei) form the suborder Plagiostomi of Elasmobranch fishes, and are divided into six families (see Ichthyology).

The first family, Pristidae, contains only the saw-fishes (Pristis), of which five species are known, from tropical and subtropical seas. They frequent especially estuaries and river-mouths, and in some cases make their way over a hundred miles from the sea. Although saw-fishes possess all the essential characteristics of the rays proper, they retain the elongate form of the body of sharks, the tail being excessively muscular and the sole organ of locomotion. The "saw" (fig. 1) is a flat prolongation of the snout, with an endoskeleton which consists of three to five cartilaginous tubes; these are the rostral processes of the cranial cartilage and are found in all rays, though commonly much shorter. The integument of the saw is hard, covered with shagreen; and a series of strong teeth, sharp in front and flat behind, are embedded in it, in alveolar sockets, on each side.

The saw is a formidable weapon of offence by means of which the fish tears pieces of flesh off the body of its victim, or rips open its abdomen to feed on the intestines. The teeth proper, with which the mouth is armed, are extremely small and obtuse, and unsuitable for wounding or seizing animals. Saw-fishes are abundant in the tropics; in their stomachs pieces of intestines and fragments of cuttle-fish have been found. They grow to a large size, specimens with saws 6 ft. long and 1 ft. broad at the base being common.

The rays of the second family, Rhinobatidae, bear a strong resemblance to the saw-fishes, but lack the saw. Their teeth are consequently more developed, flat, obtuse, and adapted for crushing hard-shelled marine animals. There are about twenty known species, from tropical and subtropical seas.

The third family, Torpedinidae, includes the electric rays. For the peculiar organ (fig. 2) by which the electricity is produced, see Ichthyology. The fish uses this power voluntarily either to defend itself or to stun or kill the smaller animals on which it feeds. To receive the shock, the object must complete the galvanic circuit by communicating with the fish at two distinct points, either directly or through the medium of some conducting body. The electric currents created in these fishes exercise all the other known powers of electricity: they render the needle magnetic, decompose chemical compounds and emit the spark. The dorsal surface of the electric organ is positive, the ventral negative. Shocks from a large healthy fish will temporarily paralyse the arms of a strong man. The species of the genus Torpedo are distributed over the coasts of the Atlantic, Pacific and Indian Ocean, and at least one reaches the coasts of Great Britain (T. thornensis). On the west coast of North America T. californica occurs, while on the Atlantic coast there is found the black crampfish (T. occidentalis). This latter is said to reach a weight of 200 lb, but such gigantic specimens are scarce, and prefer sandy ground at some distance from the shore, where they are not disturbed by the agitation of the surface-water. Seven genera with about fifteen species have been described, mostly from the warmer seas. All the rays of this family have, like electric fishes generally, a smooth and naked body.

The fourth family, Raiaidae, comprises the skates and rays proper, or Raia. More than thirty species are known, chiefly from the temperate seas of both hemispheres, but much more numerously from the northern than the southern. A few species descend to a depth of nearly 900 fathoms, while, however, essentially differing from their surface congeners. Rays, as is
indicated by their shape, are bottom-fishes, living on flat sandy ground, generally at no great distance from the coast or the surface. They lead a sedentary life, progressing, like the flat-fishes, by an undulatory motion of the greatly extended pectoral fins, the thin slender tail having lost the function of an organ of locomotion, and acting merely as a rudder. They are carnivorous and feed exclusively on molluscs, crustaceans and fishes. Some of the species possess a much larger and more pointed snout than the others, and are popularly distinguished as "skates." The following are known as inhabitants of the British seas:—

1. short-snouted species: (i) the thornback (R. clavata), (ii) the homelyn or spotted ray (R. maculata), (iii) the starry ray (R. radiata), (iv) the cuckoo or sandy ray (R. circularis); (v) long-snouted species: (g) the common skate (R. oitis), (f) the flapper skate or jumboskate (R. macrorhynchus), (g) the burton skate (R. alba), (8) and (9) the shagreen skates (R. oxyrhynchus and R. fulonica). A few deep-sea species are known, including R. abyssicola from 1588 fathoms off the coast of British Columbia. Most of the skates and rays are eaten, except during the breeding season; and even the young of the former are esteemed as food. The skates attain to a much larger size than the rays, viz. to a width of 6 ft. and a weight of 400 and 500 lb.

The members of the fifth family, Trygonidae or sting-rays, are distinguished from the rays proper by having the vertical fins replaced by a strong spine attached to the upper side of the tail. Some sixty species are known, which inhabit tropical more than temperate seas, some species being found in great tropical rivers over 1000 m. from the sea. The spine is barbed on the sides and is a most effective weapon of defence; by lashing the tail in every direction the sting-rays can inflict dangerous or at least extremely painful wounds. The danger arises from the lacerated nature of the wound rather than from any specially poisonous property of the mucus inoculated. Generally only one or two spines are developed. Sting-rays attain to about the same size as the skates and are eaten on the coasts of the Mediterranean and elsewhere. One species (Trygon pastinaca) is not rarely found in the North Atlantic and extends northwards to the coasts of Ireland, England and Norway.

The rays of the sixth and last family, Myliobatidae, are popularly known under various names, such as "devil-fishes," "sea-devils," and "eagle-rays." In them the dilatation of the body, or rather the development of the pectoral fins, is carried to an extreme, whilst the tail is very thin and sometimes long like a whip-cord (fig. 3). Caudal spines are generally present and perfectly flat molars, adapted for crushing hard substances. In some of the eagle-rays the molars are large and tessellated (fig. 4), in others extremely small. Of the twenty-seven species which are known, from tropical and temperate seas, the majority attain a very large and some an enormous size: one mentioned by Risso, which was taken at Messina, weighed 1250 lb. A foetus taken from the uterus of the mother (all eagle-rays are viviparous), captured at Jamaica and preserved in the British Museum, is 5 ft. broad and weighed 20 lb. The mother measured 15 ft. in width and as many in length, and was between 3 and 4 ft. thick. At Jamaica, where these rays are well known under the name of "devil-fishes," they are frequently attacked for sport's sake, but their capture is uncertain and sometimes attended with danger. The eagle-ray of the Mediterranean and Atlantic (Myliobatis aquila) is occasionally found off the British coasts.

RAY, J.

RAY (or Wray, as he wrote his name till 1670), JOHN (1628-1705), sometimes called the father of English natural history, was the son of the blacksmith of Black Notley near Braintree in Essex, where he was born on the 29th of November 1628, or, according to other authorities, some months earlier. From Braintree school he was sent at the age of sixteen to Catharine Hall, Cambridge, whence he removed to Trinity College after about one year and three-quarters. His tutor at Trinity was Dr. James Duport (1606-1679), regius professor of Greek, and his intimate friend and fellow-pupil the celebrated Isaac Barrow. Ray was chosen minor fellow of Trinity in 1649, and in due course became a major fellow on proceeding to the master's degree. He held many college offices, becoming successively lecturer in Greek (1651), mathematics (1653), and humanity (1655), praelector (1657), junior dean (1657), and college steward (1659 and 1660); and according to the habit of the time, he was accustomed to preach in his college chapel and also at Great St. Mary's before the university, long before he took holy orders. Among his sermons preached before his ordination, which was not till the 23rd of December 1660, were the famous discourses on The Wisdom of God in the Creation, and on the Chaos, Deluge and Dissolution of the World. Ray's reputation was high also as a tutor; and he communicated his own passion for natural history to several pupils, of whom Francis Willughby is by far the most famous.

Ray's quiet college life closed when he found himself unable to subscribe to the Act of Uniformity of 1661, and was obliged to give up his fellowship in 1662, the year after Isaac Newton had entered the college. We are told by Dr. Derham in his Life of Ray that the reason of his refusal "was not (as some have imagined) his having taken the 'Solemn League and Covenant,' for that he never did, and often declared that he ever thought it an unlawful oath; but he said he could not declare for those that had taken the oath that no obligation lay upon them, but feared there might." From this time onwards he seems to have depended chiefly on the bounty of his pupil Willughby, who made Ray his constant companion while he lived, and at his death left him £60 a year, with the charge of educating his two sons.
In the spring of 1663 Ray started together with Willughby and two other pupils on a tour through Europe, from which he returned in March 1666, parting from Willughby at Montpellier whence the latter continued his journey into Spain. He had previously in three different journeys (1658, 1661, 1662) travelled through the greater part of Great Britain, and selections from his private notes of these journeys were edited by George Scott in 1760, under the title of Mr Ray's Itineraries. Ray himself published an account of his foreign travel in 1673, entitled Observations topographical, moral, and physiological, made on a Journey through part of the Low Countries, Germany, Italy, and France. From this tour Ray and Willughby returned laden with collections, on which they meant to base complete systematic descriptions of the animal and vegetable kingdoms. Willughby undertook the former part, but, dying in 1672, left only a few pages of his compilation, which he had composed in and about the latter part of 1670. Ray, according to his great Historia plantarum (3 vols., 1686, 1688, 1704). The plants gathered on his British tours had already been described in his Catalogus plantarum Angliae (1676), which work is the basis of all later English floras.

In 1667 Ray was elected a fellow of the Royal Society, and in 1669 he published in conjunction with Willughby his first paper in the Philosophical Transactions on Experiments concerning the Motion of Sap in Trees. They demonstrated the ascent of the sap through the wood of the tree, and supposed the sap to precipitate a kind of white coagulum or jelly, which may be well conceived to be the part which every year between bark and tree turns to wood and of which the leaves and fruits are made. Immediately after his admission into the Royal Society he was induced by Bishop John Wilkins to translate his Real Character into Latin. He actually completed a translation, which, however, remained in manuscript; his Methodus plantarum nova was in fact undertaken as a part of Wilkins's great classificatory scheme.

In 1673 Ray married Margaret Oakley of Launton (Oxford); in 1676 he went to Sutton Coldfield, and in 1677 to Falborne Hall in Essex. Finally, in 1679, he removed to Black Notley, where he afterwards remained. His life there was quiet and uneventful, but embittered by bodily weakness and chronic sores. He occupied himself in writing books and in keeping up a wide scientific correspondence, and lived, in spite of his infirmities, to the age of seventy-six, dying at Black Notley on the 17th of January 1705. The Ray Society, for the publication of works on natural history, was founded in his honour in 1844.

Ray's first book, the Catalogus plantarum circa Cantabrigiam nascenium (1660, followed by appendices in 1663 and 1665), was written in conjunction with John Nid. The plants, 626 in number, are enumerated alphabetically, but a system of classification differing little from Caspar Baulin's is sketched at the end of the book; and the notes contain many curious references to other parts of natural history. The stations of the plants are minutely described; and Cambridge students still gather some of their rarer plants in the copses on chalk-pits where he found them. The book shows signs of John Ray's independent character, for which he had died in 1657, leaving his writings unpublished; but a MS. copy of some of these, sent to Ray by Samuel Hartlib in 1660. Jung invented or gave precision to many technical terms which Ray and others at once used, thus embalming for posterity a phraseological kernel of the methodical systems of the age. His notions of what constitutes a specific distinction and what characters are valueless as such seem to have been adopted with little change by Ray. The first two editions of the Catalogus plantarum, that is, the first three volumes, were based on Nid's work; but in the Synopsis stirpium Britannicarum (1660, 1666, also re-edited by Dilenius, 1724, and by Hill, 1760) Ray applied the scheme of classification which he had by that time elaborated in the Historia insigniorum plantarum, or the Dictionarium plantarum, and published in 1662. The Methodus plantarum nova (1662) was largely based on the works of Caselipinus and Jung, and still more on that of Robert Morison of Oxford. The greatest merit of this book is the use of the number of coyledons as a basis of classification; though it must be remembered that the difference between the monocotyledons and dicotyledons

**RAYAH** (Arabic راية, peasants, subjects, flock, herd, را, to pasture, cf. "ryot," an Indo-Persian variant of the same word), the name given to the non-Moslem subjects of a
Mahomedan ruler; all who pay the harai or poll-tax levied on unbelievers. Five classes of rayahs existed under Turkish rule, (1) the Gagans, (2) the Armenians or Emeni milleti; (3) the Catholic Armenians—remenii gatoliki milleti; (4) the Latin Christians, or Roum gatoliki milleti; and (5) the Jews, or ichendi milleti. The name rayah is most commonly used of the peasants, but it does not apply only to the agricultural populations. It depended on status, fixed by religious faith.

RAYELEFTHE, JOHN WILLIAM STRUTT, 3rd baron (1824—1892), English physicist, was born in Essex on the 12th of November 1842, being the son of the 2nd baron.1 Going to Trinity College, Cambridge, he graduated as senior wrangler in 1863, and obtained the first Smith's prize of the year, the second being gained by Professor Alfred Marshall. He married in 1871 a sister of Mr A. J. Balfour, and succeeded to the title in 1873. From 1879 to 1884 he was Cavendish professor of experimental physics in the university of Cambridge, in succession to Clerk Maxwell; and in 1887 he accepted the post of professor of natural philosophy at the Royal Institution of Great Britain, which he resigned in 1905. His early mathematical and physical papers, written under the name of J. W. Strutt, made him known over Europe; and his powers rapidly matured until, at the death of Clerk Maxwell, he stood at the head of British physicists, Sir George Stokes and Lord Kelvin alone excepted. The special feature of his work is its extreme accuracy and definiteness; he combines the highest mathematical acumen with refinement of experimental skill, so that the idea of ranking him as higher in one department than another does not arise. His experimental investigations are carried out with plain and usually home-made apparatus, the accessories being crude and rough, but the essentials thoughtfully designed so as to compass in the simplest and most perfect manner the special end in view. A great part of his theoretical work consists in resurveying things supposed superficially to be already known, and elaborating their theory into precision and completeness. In this way he has gone over a great portion of the field of physics, and in many cases has either said the last word for the time being, or else started new and fruitful developments. Possessing an immense range of knowledge, he has filled up lacunae in nearly every part of physics, by experiment, by calculation, and by clear accurate thought. The following branches have especially felt his influence:—chemical physics, capillarity and viscosity, theory of gases, flow of liquids, photography, optics, colour vision, wave theory, electric and magnetic problems, electrical measurements, elasticity, sound and hydrodynamics. The numerous scientific memoirs in which his original work is set forth were collected under his own editorship in four large volumes, the last of which was published in 1903. His most extensive single work is a book on Sound, which, in the second edition, has become a treatise on vibrations in general. His familiarity with the methods of mathematical analysis and a certain refinement of taste in the treatment of the subject have led to his doing this in a very beautiful form. His papers are often difficult to read, but never diffuse or tenuous; his mathematical treatment is never needlessly abstruse, for when his analysis is complicated it is only so because the subject-matter is complicated. Of discoveries superficially sensational there are few or none to record, and the weight of his work is for the most part to be appreciated only by professional physicists. One remarkable discovery, however, of general interest, was the outcome of a long series of delicate weighings and minute experimental care in the determination of the relative density of nitrogen gas—undertaken in order to determine the atomic weight of nitrogen—namely, the discovery of argon, the first of a series of new substances, chemically inert, which occur, some only in excessively minute quantities, as constituents of the air. The barony was created at George IV's coronation in 1821 for the services of Joseph Holden Strutt, M.P. for Maldon (1790-1826) and Okehampton (1826-1830), who had done great service during the French War as colonel of the Essex militia. He died in 1845, his wife, the baroness, predeceasing him in 1836. Their son (d. 1873) was the 2nd baron.

RAYLEIGH, LORD—RAYMOND OF SABUNDE

933

earth's atmosphere. Lord Rayleigh had an interest in abnormal psychological investigations, and became a member and vice-president of the Society for Psychical Research. He was one of the original members of the Order of Merit, instituted in conjunction with the coronation of King Edward VII. In 1904 he was awarded a Nobel prize, and at the end of 1905 he became president of the Royal Society, of which he had been elected a fellow in 1873, and had acted as secretary from 1885 to 1896. He remained president till 1908, in which year he was chosen to succeed the 8th duke of Devonshire as chancellor of Cambridge University.

For a popular but authentic account of some of Lord Rayleigh's scientific work and discoveries, see an article by Sir Oliver Lodge in the National Review for September 1898.

RAYMOND, HENRY JARVIS (1820—1896), American journalist, was born near the village of Lima, Livingston county, New York, on the 24th of January 1820. He graduated from the university of Vermont in 1840. After assisting Horace Greeley (q.v.) in the conduct of more than one newspaper, Raymond in 1851 formed the firm of Raymond, Jones & Co., and the first issue of the New York Times appeared on the 18th of September 1851; of this journal Raymond was editor and chief proprietor until his death. Raymond was a member of the New York Assembly in 1850 and 1851, and in the latter year was speaker. He supported the views of the radical anti-slavery wing of the Whig party in the North. His nomination over Greeley on the Whig ticket for lieutenant-governor in 1854 led to the dissolution of the famous political "firm" of Seward, Weed and Greeley. Raymond was elected, and served in 1854—56. He took a prominent part in the formation of the Republican party, and drafted the famous "Address to the People" adopted by the Republican convention which met in Pittsburg on the 22nd of February 1856. In 1862 he was again a member, and speaker, of the New York Assembly. During the Civil War he supported Lincoln's policy in general, though deprecating his delays, and he was among the first to urge the adoption of a broad and liberal attitude in dealing with the people of the South. In 1865 he was a delegate to the National Republican Convention, and was made a member, and chairman, of the Republican National Committee. He was a member of the National House of Representatives in 1865—67, and on the 22nd of December 1865 he ably attacked Thaddeus Stevens's theory of the "dead" states and, agreeing with the President, argued that the states were never out of the Union, inasmuch as the ordinances of secession were null. In consequence of this, of his prominence in the Loyalist (or National Union) Convention at Philadelphia in August 1866, and of his authorship of the "Address and Declaration of Principles," issued by the convention, he lost favour with his party. He was removed from the chairmanship of the Republican National Committee in 1866, and in 1867 his nomination as minister to Austria, which he had already refused, was rejected by the Senate. He retired from public life in 1867 and devoted his time to newspaper work until his death in New York city on the 18th of June 1869. Raymond was an able and polished public speaker; one of his best known speeches was a greeting to Kossuth, whose cause he warmly defended. But his great work is in elevating the style and general tone of American journalism. He published several books, including a biography of President Lincoln—The Life and Public Services of Abraham Lincoln (1865), which in substance originally appeared as A History of the Administration of President Lincoln (1864). See Augustus Maverick, Henry J. Raymond and the New York Press for Thirty Years (Hartford, Conn., 1870); and "Extracts from the Journal of Henry J. Raymond," edited by his son, Henry H. Raymond, in Scribner's Monthly, xix. and xx. (New York, 1870—71).

RAYMOND OF SABUNDE, or SABINDE (d. 1434), Spanish scholar, was a teacher of medicine and philosophy and finally regius professor of theology at Toulouse. His Liber naturae sive creaturarum, &c. (written 1434—36), marks an important stage in the history of Natural Theology. The book was directed against the position then generally held, that reason and faith,
RAYMUND OF ANTIQUE—RAYMUND OF TOULOUSE

philosophy and theology were antithetical and irreconcilable. Raymund declares that the book of Nature and the Bible are both Divine revelations, the one general and immediate, the other specific and mediate. The *Editio Princeps* of the book, which found many imitators, is outdated but probably belongs to 1484; there are many subsequent editions, one by J. F. von Seidel as late as 1832. In 1569 the *Prologus* was put on the Index for its declaration that the Bible is the only source of revealed truth. Montaigne (*Essays*, bk. ii. ch. xii., "An Apologie of Raymond Sebond ") tells how he translated the book into French and found "the conceits of the author to be excellent, the contexture of his work well followed, and his project full of pietie. . . . His drift is bold, and his scope adventurous, for he undertakes by humane and natural reasons, to establish and verify all the articles of Christian religion against Atheists.

See D. Beulet, *Un Inconnu célèbre: recherches historiques et critiques sur le roumain de *raymond sebond* (1175).*

RAYMUND, prince of Antioch (1097-1140), was the son of William VI, count of Poitou. On the death of Bohemund II. of Antioch (q.v.), the principality devolved upon his daughter, Constance, a child of some three years of age (1130). Fulk, the king of Jerusalem, and, as such, guardian of Antioch, was concerned to find a husband for her, and sent envoys to England to offer her hand to Raymund, who was then at the court of Henry I. Raymund accepted the offer, and stealing in disguise through southern Italy, for fear of apprehension by Roger of Sicily, who claimed the inheritance of Antioch as cousin of Bohemund I., he reached Antioch in 1133. Here he was married to Constance by the patriarch, but not until he had done him homage and fealty. The marriage excited the indignation of Alice, the mother of Constance, who had been led by the patriarch to think that it was she whom Raymund desired to wed; and the new prince had thus to face the enmity of the princess dowager and her party. In 1137 he had also to face the attacks of the eastern emperor, John Comnenus, who had come south partly to recover Cilicia from Leo, the prince of Armenia, but partly, also, to assert his rights over Antioch. Raymund was forced to do homage, and even to promise to cede his principality as soon as he was recompensed by a new fief, which John promised to carve for him in the Mahomedan territory to the east of Antioch. The expedition of 1138, in which Raymund joined with John, and which was to conquer this territory, naturally proved a failure: Raymund was not anxious to help the emperor to acquire new territories, when their acquisition only meant for him the loss of Antioch; and John had to return unsuccessful to Byzantium, after vainly demanding from Raymund the surrender of the citadel of Antioch. There followed a struggle between Raymund and the patriarch. Raymund was annoyed by the homage which he had been compelled to pay to the patriarch in 1135; and the dubious validity of the patriarch’s election offered a handle for opposition. Eventually Raymund triumphed, and the patriarch was deposed (1139). In 1142 John Comnenus returned to the attack; but Raymund refused to recognize or renew his previous submission; and John, though he ravaged the neighbourhood of Antioch, was unable to effect anything against him. When, however, Raymund demanded from Manuel, who had succeeded John in 1143, the cession of some of the Cilician towns, he found that he had met his match. Manuel forced him to a humiliating visit to Constantinople, during which he renewed his oath of homage and promised to receive a Greek patriarch. The last event of importance in Raymund’s life was the visit to Antioch in 1148 of Louis VII. and his wife Eleanor, Raymund’s niece. Raymund sought to prevent Louis from going south to Jerusalem, and to induce him to stay in Antioch and help in the conquest of Aleppo and Caesaeres. Perhaps for this end he acquired an influence over his niece, which was by some interpreted as a guilty intimacy. At any rate Louis hastily left Antioch, and Raymund was balked in his plans. In 1149 he fell in battle during an expedition against Nureddin. Raymund is described by William of Tyre (the main authority for his career) as handsome and affable; pre-eminent in the use of arms and military experi-

ence; *literaturum, itae ipse illustrius esset, cultor* (he caused the *Chanson des chétils* to be composed); a regular churchman and a faithful husband; but headstrong, irascible and unreasonable, with too great a passion for gambling (bk. xiv. c. xxi.).

For his career see, in the *Revue de l’orient latin*, vol. iv. (E. Br.)

RAYMUND OF TOULOUSE (sometimes also called Raymund of St. Giles, after a town to the south of Nimes), count of Provence, one of the leaders of the first Crusade. According to an Armenian authority, he had lost an eye on a pilgrimage to Jerusalem before the first Crusade; but the statement probably rests on the fact that he was one-eyed, *vir monoculus*. He is also recorded to have fought against the Moors in Spain before 1096; and it is certain that he was the first of the princes of the West to take the cross after Pope Urban’s sermon at Clermont. The oldest and the richest of the crusading princes, the count of Provence started, at the end of October 1096, with a large company, which included his wife, his son, and Adhemar, bishop of Puy, the Papal Legate. His march lay by Rangua and Scutari to Durazzo, whence he struck eastward, along the route also used by Bohemund, to Constantinople. At the end of April 1097 he was with difficulty induced to take a somewhat negative oath of fealty to Alexius; for the obstinacy which was one of his characteristics, coupled perhaps with some hope of acquiring new territories, made him reluctant to submit like the other crusaders to Alexius. He was present at Nicaea and Dorylaeum; but he first showed his hand in October 1097, when, as the army neared Antioch, and a rumour was spread that Antioch had been deserted by the Turks, he sent a detachment in advance to occupy the city—an action which presaged his future difficulties with Bohemund, the would-be prince of Antioch. In the siege of Antioch (which was far from having been deserted) Raymund played his part. When the city was taken by Bohemund (June 1098), the count garrisoned the Palatium Cimabbi (the palace on the miry, Yagi Sinan) of Antioch, and the tower over the Bridge Gate. He lay ill during the second siege of Antioch by Kerbogha; but in his camp a great spiritualistic activity culminated in the discovery of the Holy Lance by the Provençals. The miracle stimulated the crusaders to defeat Kerbogha: the Lance itself, discovered by the Provençals and carried hencethrough by their count, became a valuable asset in Raymund’s favour; and he began to put difficulties in the way of Bohemund’s retention of Antioch, obstinately alleging the oath to Alexius, and refusing to surrender the positions in the city which he had occupied. A struggle thus arose between the Provençals and the Normans, partly with regard to the genuineness of the Lance, which the Normans naturally doubted, and partly with regard to the possession of Antioch—the real issue at stake. Raymund was the first of the princes to leave Antioch, moving southward in the autumn of 1098 to the siege of Marra, but leaving a detachment of his troops in Antioch. With Bohemund left behind in Antioch; with the possession of the Holy Lance to give him prestige; and with the wealth which he had at his disposal, the count of Provence now definitely began to figure as the leader of the Crusade. If he could have consented to leave Bohemund in possession of Antioch and push southward, he might have achieved much. But he could not stomach the greatness of Bohemund; and when the Normans turned his troops out of Antioch in January 1099, he marched from Marra (which had been captured in December 1098) into the emirate of Tripoli, and began the siege of Arca (February 1099), evidently with the idea of founding a power in Tripoli which would check the expansion of Bohemund’s principality to the south. The siege of Arca was protracted; and the selfish policy of the count, which thus deferred the march to Jerusalem, lost him all support from the mass of the crusaders. A wave of indignation in the ranks, and the inducements which the emir of Tripoli offered to the other princes, forced Raymund to desist from the siege (May 1098), and to march southwards to Jerusalem. After the capture of Jerusalem, Raymund was offered, but refused, the advocacy of the Holy Sepulchre. He alleged his reluctance to rule in the city in which Christ had suffered:
it is perhaps permissible to suspect that he fancierd for the
principality of Tripoli and the renewal of hostilities with
Bohemund. As at Antioch, so at Jerusalem, he fell into strife
with the new ruler; and it was only with difficulty that Godfrey
was able to secure from him the possession of the Tower of
David, which he had originally occupied. The grasping nature
of Raymond again appeared after the battle of Ascalon, when
his eagerness to occupy Ascalon for himself prevented it from
being occupied at all; while Godfrey also blamed him for the
failure of his army to capture Arsuf. It almost seems as if the
counter could not appear without becoming a centre of storms;
and when he went north, in the winter of 1099-1100, his first
act was one of hostility against Bohemund, from whom he
helped to wrest Laodicea. From Laodicea he went to Con-
stantinople, where he fraternized with Alexius, the great enemy
of his own enemy Bohemund. Joining in the ill-fated Crusade
which followed in the wake of the First, he was successful in
escaping from the débâcle, and returning to Constantinople. In
1102 he came by sea from Constantinople to Antioch, where he
was imprisoned by Tancred, regent of Antioch during the
captivity of Bohemund, and only dismissed upon promising not
to attempt any conquests in the country between Antioch and
Acre. He broke his promise, attacking and capturing Tortosa,
and beginning to build a castle for the reduction of Tripoli (on
the Mons Peregrinus). In this policy he was aided by Alexius,
who was naturally willing to see the erection of a tributary
county of Bohemund to the south of Bohemund's principality. In
1105 Raymond died. He was succeeded by his nephew William,
who in 1109, with the aid of Baldwin I., captured the town and
definitely established the county of Tripoli. William was
ousted in the same year by Raymond's eldest son Bertrand;
and the county continued in the possession of his house during
the 12th century. 1
Raymond of Toulouse represents the Provençal element in
the first Crusade, as Bohemund represents the Norman, and
Godfrey and Baldwin the Lotharingian. Religion, obstinacy
and greed seem curiously blended in his composition. The first
quality appears in the episode of the Lance, and in his renuncia-
tion of the advocacy of Jerusalem: the second appears in the
whole of his attitude to Bohemund: the third appears again and
again, whenever the progress of the Crusades brought any
new conquest. If in temperament he is the least attractive
among the princes of the first Crusade, he was yet one of its
founders; and it was he who left his mark upon history in the
foundation of the county of Tripoli.

Raymond of Agiles, a clerk in the Provençal army, gives the
history of the first Crusade from his master's point of view. For
a modern account of Count Raymond's part in the crusading
movement, one may refer to Röhrich's works (see Crusades).

(E. Br.)

RAYMOND OF TRIPOLI, the most famous of the descendants
of Raymond of Toulouse, was a great-grandson of his eldest son
Bertrand: his mother was Hodiliena, a daughter of Baldwin II.,
and through her he was closely connected with the kings of
Jerusalem. He became count of Tripoli in 1132, on the assump-
tion of his father. In 1135 he captured Nur-eddin, and was only released in 1172 after a captivity of 40 years. In 1174 he claimed the regency on behalf of Baldwin IV.
(at once a minor and a leper), in virtue of his close relationship;
and the claim was acknowledged. After two years the regency
seems to have passed to Reginald of Châtillon; but Raymond,
who had married the heiress of the county of Tiberias, continued
to figure in the affairs of the kingdom. His great ability proc-
cured him enemies; for two years, 1180-1182, Baldwin IV. was
induced by evil advisers to exclude him from his territories.
But as Saladin grew more threatening, Raymond grew more
indispensable; and in 1184 he became regent for Baldwin V.,
on condition that, if the king died before his majority, his
successor should be determined by the great powers of the West.
Raymond conducted the regency with skill, securing a truce from
Saladin in 1185; but when Baldwin V. died, in 1186, all went
wrong. Raymond summoned an assembly of the barons to
Naples to deliberate on the situation; but while they deliber-
at, the supporters of Guy de Lusignan (the husband of Baldwin
IV.'s sister, Sibylia) acted, and had him crowned, in defiance of
the stipulation under which Raymond had become regent.
The rest of the barons came over to Guy; and Raymond, left in
isolation, retired to Tiberias and negotiated a truce for himself
with Saladin. His ambiguous position led contemporaries to
accuse him of treasonable correspondence with Saladin; but his
loyalty to the Christian cause was nobly shown in 1187, when
he reconciled himself to Guy, and aided him in the battle of
Hattin, which was engaged, however, in the teeth of his earnest
advice. He escaped from the battle wounded, and ultimately
retired to Tripoli, where he died (1187).

In the corrupt society of the latter days of the kingdom of
Jerusalem, Raymond showed himself at least as disinterested as
any other man, and certainly more capable than the rest of
his contemporaries. He might have saved Jerusalem, if Jerusalem
could have been saved; but his was the vox clamantis in desert.
RAYNALD of Châtillon—RAYNOUARD

by Sainte-Beuve (Nouveaux liquides, xi) to have been composed chiefly by Clermont Tonnerre and Pierre V. Malouet, and it was regarded, even by moderate men, as ill-timed. The published Lettre de l'abbé Raynal à l'Assemblée nationale (10th Dec. 1790) was really the work of the comte de Guibert. During the Terror Raynal lived in retirement at Passy and at Montlhéry. On the establishment of the Directory in 1795 he became a member of the newly organized Institute of France. He died in the next year on the 6th of March at Chailloit.

A detailed bibliography of his works and of those falsely attributed to him will be found in Quérard's La France littéraire, and the same author's Supercheres dénouées; the biography by A. Jay, prefixed to Peuchet's edition (Paris, 10 vols, 1820-1821) of the Histoire... des Indes, is of some value. To this edition Peuchet added two supplementary volumes on colonial development from 1785 to 1824. See also the anonymous Raynal démasqué (1791); Cherbal Montréal, Éloge... de G. T. Raynal (an. IV.); a notice in the Moniteur (s vendémaire, an. V.); B. Lunet, Biographie de l'abbé Raynal (Rodez, 1866); and J. Morley, Diderot (1891).

RAYNALD of Châtillon (d. 1187), a knight in the service of Constance, princess of Antioch, whom she chose for her husband in 1153, four years after the death of her first husband, Raymund (q.v.). One of Raynal's first acts was a brutal assault on the patriarch of Antioch; while two years later he made an unjustifiable attack on Cyprus, in the course of which the island was ravaged. The act brought its punishment in 1159, when he had to humiliate himself before the emperor Manuel, doing homage and promising to accept a Greek patriarch; and when Manuel came to Antioch in the same year, and was visited there by Baldwin III, Raynal led his horse into the city. Later in the year he was captured by the Mahomedans, during a plundering raid against the Syrian and Armenian peasants of the neighbourhood of Marash, and confined at Aleppo. His captivity lasted seventeen years. Released in 1176, he married Stephanie, the widow of Humphrey of Toron, and heiress of Krak and Mont Royal, to the S.E. of the Dead Sea—fortresses which controlled the trade-routes between Egypt and Damascus, and gave him access to the Red Sea. In November 1177, at the head of the army of the kingdom, he won a victory over Saladin, who only escaped with difficulty from the pursuit. But in 1181 the temptation of the caravans which passed by his fortress proved too strong, and in spite of a truce between Saladin and Baldwin IV. he began to plunder. Saladin demanded reparations from Baldwin IV. Baldwin could only reply that he was unable to coerce his unruly vassal. The result was a new outbreak of war between Saladin and Baldwin. In the spring of this year, Raynal launched ships on the Red Sea, partly for buccaneering, partly, it seems, with the design of attacking Mecca, and of challenging Mahommedanism in its own holy place. His ships were captured by one of Saladin's officers; and at the end of the year Saladin himself attacked Raynal in his fortress of Krak, at a time when a number of guests were assembled to celebrate the marriage of his stepson, Humphrey of Toron. The siege was raised, however, by Count Raymund of Tripoli; and till 1186 Raynal was quiet. In that year he espoused the cause of Sibylla and Guy de Lusignan against Count Raymund, and his influence contributed to the recognition of Guy as king of Jerusalem. His policy at this crisis was not conceived in the best interests of the kingdom; and a step which he took at the end of the year was positively fatal. Hearing of a rich caravan, in which the sister of Saladin was travelling, he swooped down from his fortress upon it. Thus the famous Edmond of the Crusades, who broke a two-year truce between the king and Saladin. Guy could not extort from him the satisfaction which Saladin demanded; Raynal replied that he was lord in his lands, and that he had no peace with Saladin to respect. Saladin swore that Raynal should perish if ever he took him prisoner; and next year he was able to fulfill his oath. He invaded the kingdom, and, at the battle of Hittin, Raynal along with King Guy and many others fell into his hands. They were brought to his tent; and Saladin, after rebuking Raynal strongly for his treachery, offered him his life if he would become a Mahommedan. He refused, and Saladin either slew him with his own hands or caused him to be slain (for accounts differ) in the presence of his companions.

The death of Raynal caused him to be regarded as a martyr; his life only shows him to have been a brigand of great capacity. He is the apostle of the feudal liberty which the barons of the Holy Land vindicated for themselves; and he shows, in his reckless brigandage, the worst side of their character. Stevenson, Crusades in the East (Cambridge, 1907), takes a most favourable view of Raynal's career; cf. especially pp. 240-241. But his whole life seems to indicate a self-willed and selfish temper. (E. BR.)

RAYNOUARD, François Juste Marie (1761-1850), French dramatist and savant, was born at Brignoles (Provençal), on the 8th of September 1761. He was educated for the bar
and practised at Draguignan. In 1791 he went to Paris as
deputy to the Legislative Assembly, but after the fall of the
 Girondists, to whose party he was attached, he had to go
into hiding. He was, however, discovered and imprisoned in
Paris. During his imprisonment he wrote his play Caton d'Utique
(1794). Éloignons de Basilières and Les Templiers were accepted
by the Comédie Française. Les Templiers was produced in 1805,
and, in spite of the protests of Geoffroy, had a great success.
Raynuard was admitted to the Academy in 1807, and from
1817 to 1826 he was perpetual secretary. He wrote other
plays, in one of which, Les États de Blois (acted 1810),
he gave offence to Napoleon by his freedom of speech, but,
realizing that the public taste had changed and that the
romanticists were to triumph, he abandoned the stage and
gave himself up to linguistic studies. He was admitted to the
Academy of Inscriptions in 1815. His researches into the
Provencal
dialect were somewhat inexact, but his enthusiasm and per
severance promoted the study of the subject. His chief works
are Choix de poésies originales des troubadours (6 vols., 1816-
1821), of which the sixth volume, Grammaire comparée des
langues de l'Europe latine dans leurs rapports avec la langue des
troubadours (1821), was separately published: Lexique roman
ensélen, 1668 to 1671, which forms a valuable document
of his life at
Passy, where he died on the 29th of October 1836.

RAZGRAD, the capital of the department of Razgrad,
Bulgaria, on the river Bieli-Lom, 40 m. S.E. of the Danubian
gate of Rustchuk by the Varna-Rustchuk railroad. Pop.
(1906) 13,783, about one-third being Moslems. The railway
station is at İnebkoți, 2 m. N. Razgrad possesses a fine
mosque, built by Ibrahim Pasha in 1614. Many Turkish
emigrants emigrated after the Russo-Turkish War of 1877,
but since then the population has again increased, and the
town has a thriving agricultural and general trade. Carpet-weaving
and viticulture are important local industries. On the 13th
of June 1810 and the 14th of August 1877 Razgrad was
scene of battles between the Turks and Russians.

RAZIN, STEPHEN TIMOFEEVITCH (d. 1671), Cossack
hetman and rebel, whose parentage and date and place of birth are
unknown. We first hear of him in 1661 on a diplomatic mission
from the Don Cossacks to the Kalmuck Tatars, and in the same
year he met him on a pilgrimage of a thousand miles,
the
greater
Society
by
the
White
Sea
for
the
benefit of his soul.
. After that all trace of him is lost for six years, when
he reappears as head of a robber community established
at Panshinskoïe, among the marshes between the rivers Tishina
and Ilovlya, from whence he levied blackmail on all vessels
passing up and down the Volga. His first considerable exploit
was to destroy the great water caravan consisting of the
treasury-barges and the barges of the patriarch and the wealthy
merchants of Moscow. He then sailed down the Volga with
a fleet of thirty-five galleys, capturing the more important forts
on his way and devastating the country. At the beginning of
1668 he defeated the voivode Jakov Bezborzov, sent against
him from Astrakhan, and in the spring embarked on a predatory
expedition into Persia which lasted for eighteen months.
Sail
ing into the Caspian, he ravaged the Persian coasts from Derbend
to Baku, massacred the inhabitants of the great emporium of
Resht, and in the spring of 1669 established himself on the
isle of Sula, off which, in July, he annihilated a Persian fleet sent
to join him. Stenka, as he was generally called, had now
become a potentate with whom princes did not disdain to treat.
In August 1669 he reappeared at Astrakhan, and accepted
for a fresh offer of pardon from the tsar there; the common people
were fascinated by his adventures. The semi-Asiatic kingdom
of Astrakhan, where the whole atmosphere was predatory
and tenet s of the population were nomadic, was the natural
milieu for such a rebellion as Stenka Razin's. In 1670 Razin,
while ostensibly on his way to report himself at the Cossack
headquarters on the Don, openly rebelled against the
government, captured Cherkask, Tsaritsyn and other places, and on
the 24th of June burst into Astrakhan itself. After massacring
all who opposed him, and giving the rich bazaars of the city
over to pillage, he converted Astrakhan into a Cossack republic,
dividing the population into thousands, hundreds and tens, with
their proper officers, all of whom were selected by lot.

Razorbill, or Razor-billed Auk, known also on many parts
of the British coasts as the Marrot, Mulre, Scout, Tinker or
Willock—names which it, however, shares with the Guillemot
(g.e.) and to some extent with the Puffin (g.e.)—is a common
sea-bird of the North Atlantic, 1 resorting in vast numbers
to certain rocky cliffs for the purpose of breeding, and
returning to deeper waters for the rest of the year. It is the Alca
torda de Linnaeus 2 and most modern authors, congenic with the Gar
dowl (g.e.), if not with the true Guillemots, between which two
forms of the same species—differing from the former in its
smaller size and retaining the power of flight, which that extinct species
had lost, and from the latter in its peculiarly-shaped bill, which is
vertically enlarged, compressed, and deeply furrowed, as well as
in its elongated, wedge-shaped tail. A fine white line, running

1 Steevy.

1 Schlegel (Mus. des Pays-Bas, Uralinates, p. 14) records an example from Japan; but this must be in error.

2 The word Alca is simply the Latinized form of this bird's common Teutonic name, AIk, of which Auk is the English modification. It must therefore be held to be the type of the Linnean genus Alca, though some systematists on indefensible grounds have removed it thence, making it the sole member of a genus named by Leach, after Aldrovandus (Ornithologia, bk. xix. chap. xii.), Utamania—an extraordinary word, that seems to have originated
in some mistake from the no less extraordinary Vuttamoria, given
by Belon (Observations, i. c. xl.) as the Cretan name of some diving
bird, which could not have been the present species.
on each side from the base of the culmen to the eye, is in the adult bird in breeding-apparel (with rare exceptions) a further characteristic. Otherwise the appearance of all these birds may be briefly described in the same words—head, breast and upper parts generally of a deep glossy black, and the lower parts and tip of the secondaries of a pure white, while the various changes of plumage dependent on age or season are alike in all. In habits the razorbill closely agrees with the true guillemots, laying its single egg (which is not, however, subject to the same variety of coloration as in the guillemot) on the ledges of cliffs, but it is said as a rule to occupy higher elevations, and when not breeding to keep farther out to sea. On the east side of the Atlantic the Razorbill has its breeding stations from the North Cape to Brittany, besides several in the Baltic; while in winter it passes much farther to the southward, and is sometimes numerous in the Bay of Gibraltar, occasionally entering the Mediterranean, but apparently never extending east of Sicily or Malta. On the west side of the Atlantic it breeds from 70° N. lat. on the eastern shore of Baffin's Bay to Cape Farewell, and again on the coast of America from Labrador and Newfoundland to the Bay of Fundy, while in winter it reaches Long Island.

(See) Egypt—

RAZZIA (an adaptation of the Algerian Arabic ɣazżāh, from ghasūw, to make war), a foray or raid made by African Moslems. As used by the Arabs, the word denotes a military expedition against rebels or infidels, and razzias were made largely for punishment of hostile tribes or for the capture of slaves. English writers in the early years of the 19th century used the form ghrazzie, and Dixon Denham in his Travels (1826) styles the raiding force itself the ghrazzie. The modern English form is copied from the French, while the Portuguese variant is gazie, gaziea.

RE, the Egyptian solar god, one of the most important figures in the Pantheon. See Egyptian Religion.  

RÉ, ÎLE DE, an island of western France, belonging to the department of Charente-Inférieure, from the nearest mainland point of which it is distant about 2 m. The island has an area of nearly 33 sq. m., with a breadth varying from 1 to 43 m. and a length of 15 m. It is separated from the coast of Vendée on the N. by the Pertuis Breton, some 6 m. broad, and from the island of Oléron on the S. by the Pertuis D'Antioche, 7 1/2 m. broad. The coast facing the Atlantic is rocky and inhospitable, but there are numerous harbours on the landward side, of which the busiest is La Flotte. Towards the north-west extremity of the island there is a deep indentation, the Fier d'Arès, which leaves an isthmus only 230 ft. wide, strengthened by a breakwater. The north coast is fringed by dunes and by the salt-marshes which are the chief source of livelihood for the inhabitants. Some of these dunes are employed in fishing, oyster-cultivation and the collection of seaweed for manure; the island has corn-lands and vineyards, the latter covering almost half its surface, and produces good figs and pears. Apart from its orchards it is now woodless, though once covered by forests. There are two cantons, St Martin (pop. in 1906, 8,362) and Ars-en-Ré (pop. 4,717) forming part of the arrondissement of La Rochelle. St Martin, the capital, which has a secure harbour and trade in wine, brandy, salt, &c., was fortified by Vauban in 1681 and used to be the depot for convicts on their way to New Caledonia. In 1627 it repulsed an English force after a siege of three months.

READE, CHARLES (1814-1884), English novelist and dramatist, the son of an Oxfordshire squire, was born at Ispiden, Oxfordshire, on the 6th of June 1814. He entered Magdalen College, Oxford, proceeded B.A. in 1835, and became a fellow of the college. He was subsequently dean of arts, and vice-president of Magdalen College, taking his degree of D.C.L. in 1847. His name was entered at Lincoln's Inn in 1836; he was elected Vinian Fellow in 1842, and was called to the bar in 1843. He kept his fellowship at Magdalen all his life, but after taking his degree he spent the greater part of his time in London. He began his literary career as a dramatist, and it was his own wish that the word "dramatist" should stand first in the description of his occupations on his tombstone. He was dramatist first and novelist afterwards, not merely chronologically but in his aims as an author, always having an eye to stage-effect in scene and situation as well as in dialogue. His first comedy, The Ladies' Battle, appeared at the Olympic Theatre in May 1851. It was followed by Angelo (1851), A Village Tale (1852), The Lost Husband (1852), and Gold (1853). But Reade's reputation was made by the two-act comedy, Masks and Faces, in which he collaborated with Tom Taylor. It was produced in November 1852, and later was expanded into three acts. By the advice of the actress, Laura Seymour, he turned the play into a prose story which appeared in 1853 as Peg Woffington. He followed this up in the same year with Christie Johnstone, a close study of Scottish fisher folk, an alien extraordinaire tour de force for the son of an English squire, whether we consider the dialect or the skill with which he enters into alien habits of thought. In 1854 he produced, in conjunction with Tom Taylor, Two Loves and a Life, and The King's Rival; and, unaided, The Courier of Lyons—well known under its later title, The Lyons Mail—and Peregrine Pickle. In the next year appeared Ari, afterwards known as Nance Oldfield.

He made his name as a novelist in 1856, when he produced It's Never Too Late to Mend, a novel written with the purpose of reforming abuses in prison discipline and the treatment of criminals. He described prison life with a fidelity which becomes at times tedious and revolting; but the power of the descriptions was undeniable, and the interest was profound. The truth of some of his details was challenged, and the novelist defended himself with vigour against attempts to rebut his contentions. Five minor novels followed in quick succession,—The Course of True Love never did run Smooth (1857), Jack of all Trades (1858), The Autobiography of a Thief (1858), Love Me Little, Love Me Long (1859), and White Lies (1860), dramatically as The Double Marriage. Then appeared, in 1861, his masterpiece, The Cloister and the Hearth, relating the adventures of the father of Erasmus. He had dealt with the subject two years before in a short story in Once a Week, but, seeing its capabilities, expanded it; and the work is now recognized as one of the finest historical novels in existence. Returning from the 19th century to modern English life, he next produced another startling novel with a purpose, Hard Cash (1863), in which he strove to direct attention to the abuses of private lunatic asylums. Three more such novels, in two of which at least the moral purpose, though fully kept in view, was not allowed to obstruct the flow of incident, were afterwards undertaken,—Foul Play (1869), in which he exposed the iniquities of shipknackers, and paved the way for the labours of Samuel Plimsoll; The World's Appeal (1872), an attack on the tyrannous outrages of trades-unions; and A Woman-Hater (1877), in which he exposed the degrading conditions of village life. The Wandering Heir (1879), of which he also wrote a version for the stage, was suggested by the Tichborne trial. Outside the line of these moral and occasional works Reade produced three elaborate studies of character,—Griffith Gaunt (1866), A Terrible Temptation (1871), A Simpleton (1873). The first of these was in his own opinion the best of his novels, and his own opinion was probably right. He was wrong, however, in his own conception of his powers as a dramatist. At intervals throughout his literary career he sought to gratify his dramatic ambition, hiring a theatre and engaging a company for the representation of his own plays. An example of his persistency was seen in the case of Foul Play. He wrote this in 1869 in combination with Mr Johnston, and afterwards with a view to stage adaptation. The play was more or less a failure; but he produced another version alone in 1877, under the title of A Scuttled Ship, and the failure was pronounced. His greatest success as a dramatist attended his last attempt,—Drink—an adaptation of Zola's L'Assommoir, produced in 1879. In that year his friend Laura Seymour, who had kept house for him since 1854, died. Reade's health failed from that time, and he died on the 11th of April 1884, leaving behind him a completed novel, A Perilous Secret, which showed no falling off in the arts of weaving a complicated plot, and always thrilling situations.
Reade was an amateur of the violin, and among his works is an essay on Cremona violins with the title, *A Lost Art Revised.*

It was characteristic of Reade's open and combative nature that he admitted the public freely to the secrets of his method of composition. He spoke about his method in his prefaces; he introduced himself into one of his novels—"Dr Rolle" in *A Terrible Temptation*; and by his will he left his workshop and his accumulation of materials open for inspection for two years after his death. He had collected an enormous mass of materials for his study of human nature, from personal observation, from newspapers, books of travel, blue-books of commissions of inquiry, from miscellaneous reading. This vast collection was classified and arranged in huge ledgers and notebooks. He had planned a great work on "the wisdom and folly of nations," dealing with social, political and domestic details, and it was chiefly for this that his collection was destined, but in passing he found the materials useful as a store of incidents and suggestions. A collector of the kind was bound to be systematic, otherwise his collection would have fallen into confusion, and Reade's collection contains many curiosities in classification and tabulation. On the value of this method for his art there has been much discussion, the prevalent opinion being that his imagination was overwhelmed and stifled by it. He himself maintained the contrary; and it must be admitted that a priori critics have not rightly understood the use that he made of his laboriously collected facts. He did not merely shelve the contents of his notebooks into his novels; they served rather as an atmosphere of reality in which he worked, so that his novels were like pictures painted in the open air. His imagination worked freely among them and was quickened rather than impeded by their suggestions of things suited to the purpose in hand; and it is probably to his close and constant contact with facts, acting on an imagination naturally fertile, that we owe his marvellous abundance of incident. Even in his novels of character there is no meditative and analytic stagnation; the development of character is shown through a rapid unceasing progression of significant facts. This rapidity of movement was perhaps partly the result of his dramatic studies; it was probably in writing for the stage that he learned the value of keeping the attention of his readers incessantly on the alert. The hankering after stage effect, while it saved him from dullness, often betrayed him into rough exaggeration, especially in his comic scenes. But the gravest defect in his work is a defect of temper. His view of human life, especially of the life of women, is almost brutal; his knowledge of frailties and vices is obstructed with repellent force; and he cannot, with all his skill as a story-teller, be numbered among the great artists who warm the heart and help us to improve the conduct. But as a moral satirist, which was the function he professed over and above that of a story-teller, he did good service, both indirectly in his novels and directly in his own name.

READING, a municipal, county, and parliamentary borough and the county town of Berkshire, England, 36 m. W. by S. of London by the Great Western railway. Pop. (1901) 72,217. It is an important junction on the Great Western system, and has communication southward by a joint line of the South-Western and South-Eastern and Chatham companies. The Kennet and Avon canal, to Bath and Bristol, and the Thames, afford it extensive connexions by water. It lies in the vale of the Thames, on the south (left) bank, where the Kennet joins the main river. The population is more than doubled in the last thirty years of the 19th century, and the town is of modern appearance. All the ancient churches are much restored and in part rebuilt. Greyfriars church, formerly monastic, was completed early in the 14th century; and after the dissolution of the monasteries served successively as a town hall, a workhouse and a gaol, being restored to its proper use in 1864. St Mary's is said to have been rebuilt in 1551 from the remains of a nunnery founded by Elfrith by expiation of the murder of her stepson Edward the Martyr. St Lawrence's is a large Perpendicular building, and St Giles's, in various styles, was much damaged during the siege of the town in 1643 by the parliamentary forces, and is almost wholly rebuilt. A Bene dictine abbey was founded at Reading in 1121 by Henry I., and became one of the richest in England, with a church among the largest in the country. Its founder was buried here, but his monument was destroyed in the time of Edward VI. The church was the scene of John of Gaunt's marriage to Blanche of Lancaster in 1350. By Henry VIII. the abbey was converted into a royal palace, and was so used until its destruction during the civil wars of the 17th century. Little remains of the foundation; only a gateway and a fragment of the great hall, the meeting-place of several parliaments, are of importance. The greater part of the site is occupied by public gardens.

The educational establishments are important. The site of an ancient hospice of St John is occupied by the University Extension College. It was opened in 1892, is affiliated to Oxford University, and has accommodation for 600 students, of both sexes, giving instruction in every main branch of higher university education, agriculture, &c. The grammar school, founded in 1485, occupies modern buildings and ranks among the lesser public schools. Archbishop Laud was educated here, and became a generous benefactor of the school. There are also a blue-coat school (1556), and other charitable schools of early foundation. The municipal museum, besides an art gallery and other exhibits, includes a fine collection of Romano-British relics from Silchester, the famous site not far distant in Hampshire. Besides the public grounds on the site of the abbey there may be mentioned Prospect Park of 131 acres, purchased by the Corporation, and Palmer Park, presented by a member of the firm of Huntley & Palmer, together with extensive recreation grounds.

The industry for which Reading is chiefly famous is the biscuit manufacture, the principal establishment for which is that of Messrs Huntley & Palmer, employing about 5000 hands. In the town and its vicinity are large seed warehouses and testing-grounds. There are also iron foundries, engineering works and factories for agricultural implements, and manufactures of tin boxes, saucers, velvet and silk, and sacking, together with riverside boat-building yards. Reading gives title to a suffragan bishopric in the diocese of Oxford. The parliamentary borough returns one member. The municipal borough is under a mayor, 10 aldermen and 30 councillors. Area, 5876 acres.

Reading (Redinges, Rading, Redding) early became a place of importance. In 871 the Danes encamped here between the Thames and the Kennet, and in 1066 it was burned by Swein. It consisted of only thirty houses at the time of the Domesday Survey. There is some reason to think that a fortification existed there before the Conquest, and Stephen probably built a masonry castle which Henry II. destroyed. On the foundation of Reading abbey the town, hitherto demesne of the crown, was granted to the abbey by Henry I. Henceforth, until the 16th century, the chief feature of its history was the struggle as to rights and privileges. This was carried on between the abbey and the merchant guild which claimed to have existed in the time of the Confessor, and the chief officer of which was from the 13th century styled warden or mayor.

A 16th-century account of the guild merchant shows that many trades were then carried on, but Leland says the town "chiefly standeth by clothing." The story of Thomas Cole, written by Eelmon d. 1600, purporting to refer to the reign of Henry I., indicates that the industry was carried on at an early date. Archbishop Laud was the son of a Reading clothier. By the 17th century the trade was beginning to decline; the bequest of Kendrick "the Phoenix of worthy Benefactors" did little to revive it, and it was greatly injured by the Civil War. In the 18th century the chief trade was in malt. The first town charter is that given by Henry III. (1253) on behalf of the "burgesses in the Guild Merchant," which was confirmed and
amplified by succeeding sovereigns. The governing charter until 1835 was that of Charles I. (1639) incorporating the town under the title of the mayor, aldermen and burgesses. Reading returned two members to parliament from 1295 to 1885, when it was deprived of one; until 1832 the Scot-and-Lot franchise was used. The town surrendered to the parliamentary troops, after a siege, in 1643; it was occupied subsequently by the forces of both parties: in 1688 a skirmish took place in the town between some Irish soldiers of James II. and the troops of William of Orange. The market, chiefly held on Saturday, can be traced to the reign of Henry III.; four fairs granted by the charter of 1362 are still held, that on the 25th of July dating originally from a grant of Henry II. to Reading abbey.

See C. Coates, History of Reading (1806); Victoria County History, Berks.

READING, a city and the county-seat of Berks county, Pennsylvania, U.S.A., in the S.E. part of the state, on the E. bank of the Schuylkill river, and about 58 m. N.W. of Philadelphia. Pop. (1860) 43,278; (1890) 58,661; (1900) 78,961, of whom 5940 were foreign-born; (1910, census) 96,071. Reading is served by the Pennsylvania and the Philadelphia & Reading railways, by the Schuylkill Canal, which carries freight to Philadelphia, and by electric railways to several villages in Berks county. The city occupies the valley and alluvial deposits descending the base of Mt. Penn westward to the Schuylkill river, and therefore possesses excellent drainage facilities. The river, which is unnavigable and winding at this point, forms the western boundary of the city for more than 4 m., and is spanned by three public bridges and a number of railway bridges. Neversink Mountain (878 ft. high), lying to the S. of the city, and Mt. Penn (800 ft.), are pleasure resorts in the neighbourhood. On the neighbouring mountains are several summer hotels and sanatoria. Within the city is Penn Common, containing 50 acres, reserved by the Penns for the use of the town when it was first laid out, and since 1878 used as a public park. Mineral Spring Park, containing 63 acres, lies on the outskirts of the city. Other parks are maintained by the street railway companies. In Penn Common are a monument erected to the "First Defenders," to commemorate the fact that the "Ringgold Light Infantry," the first volunteer company to report at Washington for service in the Civil War, came from this city; a monument to President McKinley, and one to the volunteer fire companies of the city. Among interesting landmarks are the Federal Bank, in which President Roosevelt was entertained in 1904, and which has been used as a banking house since 1814; the old county gaol (1770), used as such until 1848; and the site of the "Hessian Camp," where some of the prisoners captured during the War of Independence were confined. Charitable institutions are numerous; among them are the Reading Hospital (1857), St. Joseph's Hospital (1873), Homoeopathic Hospital (1861), the Home for Widows and Single Women (1873), the Hope Rescue Mission (1897) for homeless men, the Home for Friendless Children (1888), St. Catharine's Female Orphan Asylum (1872), St. Paul's Orphan Asylum for Boys, and the House of the Good Shepherd (1889). Other institutions are the public library, which from 1808 to 1898 was a subscription library; the Berks County Law Library; the Berks County Historical Society; and the Harmonic Maennerchor, organized in 1847 and one of the oldest singing societies in the United States.

Lying within the rich agricultural region of the Lebanon and Schuylkill valleys and near vast fields of anthracite coal and iron ore, Reading possesses unusual business and industrial advantages. The chief industry is the manufacture of iron and steel. There are large shops of the Philadelphia & Reading railway here. The total value of factory products in 1905 was $90,848,175 (in 1900 it had been $32,682,061), and the most important of these were the products of steel-works and rolling-mills; the products of railway repair shops; foundry and machine-shop products; hardware, hosiery and knitted goods; cigars and cigarettes, and felt hats. Other important manufactures are bicycles, brick and other clay products, brooms, brushes, and cotton and woollen goods.

Reading was surveyed and laid out as a town in 1748, in accordance with the plans of Thomas and Richard Penn, sons of William Penn, and was named Reading after the county town of Berkshire, England. The first settlers were mostly Germans, but the direction of municipal affairs until the outbreak of the War of Independence was in the hands of the English-speaking inhabitants. As the latter were largely of Loyalist sympathies during the war, the control of the local government then fell into the hands of the German inhabitants. German was long used in Reading; Pennsylvania German (or "Dutch") is still spoken in the surrounding country; and several German periodicals are published in the city, including among them the weekly Adler since 1796. During the War of Independence Reading was an inland depot for supplies for the American army, and prisoners of war were sent here in large numbers. The development of the town dates from the opening in 1824 of the Schuylkill Canal, from Reading to Philadelphia. This was followed in 1828 by the Union Canal, running westward to Lebanon and Middletown, and in 1838 by the entrance into Reading of the Philadelphia & Reading railway. The establishment of these means of communication has in a large degree developed the natural resources of the region, and Reading early became a natural industrial centre. A system of water-works, established in 1821, was acquired by the municipality in 1865. Reading was incorporated as a borough in 1873, and was chartered as a city in 1847.

READING BEDS, in geology, a series of marine and estuarine beds consisting of variegated plastic clays and bright-coloured sands, which form, with the Woolwich beds, a subdivision of the Lower Eocene (see WOOLWICH AND READING BEDS).

READYMONEY, SIR COWASJI JEHANGIR (1852-1878), "the Peabody of Bombay." Early in the 18th century three Parsee brothers moved from Nowsari, near Surat, in Gujarat, to Bombay, and became the pioneers of a lucrative trade with China. They gained the sobriquet of "Readymoney," which they adopted as a surname. Only Hirji Jawansi Readymoney left issue, two daughters, the elder of whom married a Banaji, and the younger a Dady Sett. The son of the former, Jehangir Hirji, married Mirbæi, the daughter of the latter, and was thus the heir only of his grandmother, but of his two grand-uncles. The younger of their two sons was Cowasji Jehangir. His only English education was at the then well-known school kept by Serjeant Sykes in the Fort of Bombay. At the age of 15 he entered the firm of Duncan, Gibb & Co. as "godown keeper," or warehouse clerk. In 1837 he was promoted to the responsible and lucrative appointment of "guarantee broker" to two of the leading European firms of Bombay. In 1846 he was able to begin trading on his own account. He was made a J.P. for the town and island of Bombay, and a member of the board of conservancy; and in 1866 was appointed a commissioner of income tax, his tactful management being largely responsible for the fact that this tax, then new to Bombay and unpopular, was levied with unexpected financial success. He was made C.S.I. in 1871; and in 1872 he was created a Knight Bachelor of the United Kingdom, and his statue, by T. Woolner, R. A., was erected in the town hall. His donations to the institutions of Bombay amounted to close on £200,000. His health broke down in 1871, and he died in 1878, being succeeded by his son, Sir J. Cowasji Jehangir [Readymoney], who was created a Knight Bachelor in 1895, and a Baronet in 1898.

See J. Cowasji Jehangir, Sir Cowasji Jehangir Readymoney (1890).

(CHARLES REAGAN)

READMAN, JOHN HENNINGER (1818-1905), American politician, was born in Sevier county, Tennessee, on the 8th of October 1818. He removed to Texas in 1839, was deputy surveyor of public lands in 1839-1843, was admitted to the bar in 1846, was a member of the state House of Representatives
in 1847-1848, served as district judge in 1852-1857, and in 1857-1861 was a representative in Congress. His political views were determined by the ultra-democratic influence of Andrew Jackson and the state-sovereignty philosophy of John C. Calhoun. In 1861 he was a member of the Texas secession convention, served in the Confederate provisional Congress, and on the 6th of March was appointed postmaster-general in President Davis's cabinet. He served in this capacity throughout the war, and for a short time before its close was also acting secretary of the treasury. He was captured with the Davis party on the 10th of May 1865, and was imprisoned in Fort Warren, Boston Harbour, until the following October. While in prison he wrote the "Fort Warren letter" (August 11th), in which he urged the people of Texas to recognize their defeat, grant civil rights to the freedmen, and try to conciliate the North. From 1875 to 1887, when he entered the U.S. Senate, he was again a representative in Congress, and from 1879 almost continuously to the close of his service he was chairman of the Committee on Commerce, in which capacity he had a prominent part in securing the passage of the Interstate Commerce Act of 1887. He was a member of the state constitutional convention of 1876. In state politics his sympathies were with the Radicals. In 1891, believing that his first duty was to his state, he resigned from the Senate to accept the chairmanship of the newly established state railway commission. In 1901 he retired from public service. From 1899 until his death he was president of the Texas State Historical Association. He died at his home, near Palestine, Texas, on the 6th of March 1905.

See his Memoirs; with Special Reference to Secession and the Civil War (New York, 1906), edited by W. F. McCaleb.

REALGAR, a mineral species consisting of arsenic monosulphide (AsS) and occurring as monoclinic crystals of a bright red colour. There is a perfect cleavage parallel to the plane of symmetry (r in fig.). The lustre is resinous, and the streak has the same colour as the crystals, namely, orange-red to aurora-red. The hardness is 1-2 and the specific gravity 3.55. On exposure to light the crystals crumble to a yellow powder. The name realgar is of Arabic origin, and was used by the alchemists; the substance was known to Theophrastus under the name Σαλαράκαν, and to Pliny as Sordanarcha. The mineral usually occurs in association with the yellow arsenic sulphide, orpiment. Good crystals are found with ores of silver and lead in the mineral veins of Felsóbánya, near Nagy-Bánya, Kapnik-Bánya and Nagyá, near Déva, in Hungary; with blende in the white crystalline dolomite of the Binnenhal in Switzerland; and in a bed of sandy clay at Mercur in Utah. It is deposited by the solfataras near Naples and by the hot springs of the Yellowstone National Park. Realgar has been used as a pigment and in pyrotechny for producing a brilliant white fire, but it is now replaced by the artificially prepared compound.

The other native arsenic sulphide, As₂S₃, known as orpiment (Lat. auripigmentum, meaning "golden paint"), occurs as foliated masses of a lemon-yellow colour, the foliation being parallel to a direction of perfect cleavage. It is seetile and soft (H. = 1-2), and has a specific gravity 3.4. Distinctly developed crystals are rare; they have usually been considered to be orthorhombic and isomorphous with stibnite (Sb₂S₃), but it is probable that they are really monoclinic. Orpiment is extensively mined near Julamer in Asiatic Turkey. (L. J. S.)

REALISM (from Low Lat. realis, pertaining to res, things, as opposed to ideas and imaginations), a philosophical term used in two opposite senses. The older of these is the scholastic doctrine, traceable back to Socrates, that universals have a more "real" existence than things. Universals are, in scholastic language, ante res, in rebus and post res. Behind all numerous types of chairs there is in the mind the idea chair of which particular chairs are mere copies. In the most extreme form realism denies that anything exists in any sense except universals. It is opposed to nominalism (q.v.) and conceptualism (q.v.). For the history of the doctrine, see SCHOLASTICISM. Realism in this sense has been called "an assertion of the rights of the subject" (cf. the Protagonist maxim, "Man is the measure of all things"). The modern application of the term is to the opposing doctrine that there is a reality apart from its presentation to consciousness. In this sense it is opposed to idealism (q.v.), whether the purely subjective or that more comprehensive idealism which makes subject and object mutually interdependent. In its crude form it is known as "Natural" or "Naive" Realism. It appears, however, in more complex forms, e.g. as Ideal Realism (or Real Idealism), which combines epistemological idealism with realism in metaphysics. Again, Kant distinguishes "empirical" realism, which maintains the existence of things in space independent of consciousness, from "transcendental" realism, which ascribes absolute reality to time and space.

In literature and art "realism" again is opposed to "idealism" in various senses. The realist is (1) he who deliberately declines to select his subjects from the beautiful or harmonious, and, more especially, describes ugly things or unattractive persons; (2) he who deals with individuals, not types; (3) most properly, he who strives to represent the facts exactly as they are.

REALM, the dominions of a king, a kingdom. The O.Fr. royaume (mod. royaume) was the form first adopted in English, and the modern spelling does not appear fixed till the beginning of the 17th century. The word must be referred to a supposed Med. Lat. regalimen, from regalis, of or belonging to a rex, king.

REAL PROPERTY. The law land of England and of countries whose law is based upon that of England stands in a peculiar position, which can be understood only by an outline of its history.

History.—Such terms as "fee" or "homage" carry us back to feudal times. Rights of common and distress are based upon still older institutions, forming the very basis of primitive law. The conception of tenure is the fundamental ground of distinction between real and personal estate, the former only being strictly entitled to the name of estate (q.v.). The division into real and personal is coincident to a great extent with that into immovable and movable, generally used by systems of law founded on the Roman (see PERSONAL PROPERTY.) That it is not entirely coincident is due to the influence of the Roman law itself. The Greeks and the Romans of the republic were essentially nations of citizens; the Teutons were essentially a nation of land-folk; the Roman empire bridged the gulf between the two. It is probable that the English land law was produced by the action of the policy adopted in the lower empire, finally developed into feudalism, upon the previously existing course of Teutonic custom. The distinguishing features of the Teutonic system were enjoyment in common and the absence of private rights except to a limited extent. The principal features of the old English land law before the Conquest, from which the modern law has developed, were (1) liberty of alienation, either by will or by inter vivos, of such land as could be alienated, chiefly, if not entirely, bovland, subject always to the limits fixed by the boc; (2) publicity of transfer by enrollment in the shire-book or church-book; (3) equal partition of the estate of a deceased among the sons, and failing sons among the daughters; (4) cultivation to a great extent by persons in various degrees of servitude, owing money or labour rents; (5) variety of custom, tending to become uniform, through the application of the same principles in the local courts; (6) subjective land to the trinoda necessitas, a burden imposed for the purpose of defence of the realm. The rudiments of the conceptions of tenure and of the crown as lord paramount were found in the old English system, and ineland was an anticipation of the limited interests which afterwards became of such importance.¹ The connexion of political privileges with the ownership

¹The name has not remained as in Germany and Denmark. A fief is still Lehens in Germany, Løhn in Denmark.
of land is not peculiar to the pre-Conquest or any other period. It runs through the whole of English history.

The elements of feudalism so far existed in England under the Anglo-Saxon and Danish kings as to make it easy to introduce it in full at the Norman Conquest. What the Norman Conquest did was not to change all at once alodial into feudal tenure, but to complete the association of territorial with personal dependence in a state of society already prepared for it.1 “Nulla terre sine seigneur” was one of the fundamental axioms of feudalism. There might be any number of infeudations and subinfeudations to mesne lords, but the chain of seigniory was complete, depending in the last resort upon the king as lord paramount. Land was not owned by free owners owing only necessary militia duties to the state, but was held of the king by military service of a more onerous nature. The folkland became the king’s land; the tenant was a landowner instead of the landowner being a soldier. Free owners tended to become tenants of the lord, the township to be lost in the manor.2 The common land became in law the waste of the manor, its enjoyment resting upon a presumed grant by the lord. On the other hand, the whole of England did not need to be partitioned into manors, the township and the manor resulting in a compromise, the result of which affects English tenure to this day. But it was a compromise much to the advantage of the privileged class, for in England more than in any other country the land law is the law of the nobility and not of the people. One reason of this is that, as England was never so completely feudalized as were some of the European continental states, the burden of feudalism was not so severely felt, and has led to less agitation for reform.

The land forfeited to the Conqueror was regranted by him to be held by military service due to the king, not to the mesne lord as in European continental feudalism. In 1086 at the council of Salisbury all the landholders swore fealty to the crown. In the full vigour of feudalism the inhabitants of England were either free or not free. The free inhabitants held their lands either by free tenure (liberum tenementum, franktenement) or by a tenure which was originally that of a non-free inhabitant, but attached to land in the possession of a free man. Franktenement was either military tenure, called also tenure in knight service or chivalry (including barony, the highest tenure known to the law, grand serjeanty and the special forms of escuage, castle-guard, cornage and others) or socage (including burgage and petit serjeanty), or frankalmoign (libera eleemosyna) or divine service, by which ecclesiastical corporations generally held their land.3 The non-free inhabitants were in Domesday Book servi, cotarii or bordarii, later nativi or villani, the last name being applied to both free men and serfs. All these were in a more or less dependent condition. The free tenures all exist at the present day, though, as will appear later, the military tenures have shrunk into the unimportant and exceptional tenure of grand serjeanty. The non-free tenures are to a certain extent represented by copyhold. The most important difference between the military and socage tenures was the mode of descent. Whether or not a feudal benefice was originally hereditary, it had certainly become so at the time of the Conquest, and it descended to the eldest son. This applied at once in England to land held by military service as far as regarded the capital fief. The descent of socage lands or lands other than the capital fief for some time followed the old pre-Conquest rule of descent. Thus in the so-called “Laws of Henry I.” the lands other than the capital fief, and in Glanvill, who wrote in the time of Henry II., socage lands, if anciently partible (antiquitus divisum), were divided among all the sons equally. But the line of Bracton (Henry III.) the course of descent of lands held by military service had so far prevailed that, though it was a question of fact whether the land was partible or not, if there was no evidence either as to descent to the eldest son was presumed. Relics of the old custom still remain in the case of gavelkind. The military tenant was subject to the feudal incidents, from which the tenant in socage was exempt. These incidents, especially wardship and marriage, were often oppressive. Alienation of lands by will, except in a few favoured districts, became impossible; alienation inter vivos was restrained in one direction in the interests of the heir, in another in the interests of the lord. At the time of Glanvill a tenant had a greater power of alienation over land which he had purchased (terra acquiriata) than over land which he had inherited. But by the time of Bracton the heir had ceased to have any interest in either kind of land. The lords were more successful. It was enacted by Magna Carta that a free man should not give or sell so much of his land as to leave an amount insufficient to perform his services to his lord. In spite of this provision, the rights of the lords were continually diminished by subinfeudation until the Statute of Quia Emptores. Alienation by a tenant in chief of the crown without licence was a ground of forfeiture until 1 Edw. III. st. 2, c. 27, but the fine was subsequently reduced. The titles of conveyance at this time were only two, feufoption with livery of seisin for corporeal hereditaments, grant for incorporeal hereditaments. Livery of seisin, though public, was not officially recorded like the old English transfer of property. The influence of local custom upon the land law must have become weakened after the circuits of the judges of the King’s Court were established by Henry II. Jurisdiction over litigation touching the freehold was taken away from the lord’s courts by 15 Ric. II. c. 12.

The common law as far as it dealt with real estate had in the main assumed its present aspect by the reign of Henry III. The changes which have been made since that date have been chiefly due to the action of equity and legislation, the latter sometimes interpreted by the courts in a manner very different from the intention of parliament. The most important influence of equity has been exercised in mortgage and trusts in the doctrine of specific performance of contracts concerning real estate, and in relief from forfeiture for breach of covenant.

History of Real Estate Legislation.—The reign of Edward I. is notable for three leading statutes, all passed in the interests of the superior lords. The Statute of Mortmain (7 Edw. I. st. 2, c. 13) is the first of a long series directed against the acquisition of land by religious and charitable corporations. The statute De Donis Conditionalibus (13 Edw. I. c. 1) forbade the alienation of estates granted to a man and the heirs of his body, which before the statute became on the birth of an heir at once alienable (except in the case of gifts in frankmarriage), and so the lord lost his escheat. The statute Quia Emptores (15 Edw. I. c. 1) preserved those rights of the lords which were up to that time subject to be defeated by subinfeudation, by enacting that in any alienation of lands the alienee should hold them of the same lord of the fee as the alienor.4 Since 1290 it has been impossible to create an estate in fee-simple to be held of a mesne lord, or to reserve a rent upon a grant of an estate in fee (unless in the form of a rent-charge), or to create a new manor. The statute, however, does not bind the crown. The practical effect of the statute was to make the transfer of land hazardous of a commercial and less of a feudal transaction. The writ of ejecti was introduced by the Statute of Westminster II. in 1285 as a creditor’s remedy over real estate. It has, however, been considerably modified by subsequent legislation. From 1290 to the reign of Henry VIII., there is no statute of the first importance dealing with real estate. The reign of Henry VIII., like the reign of Edward I., is signalized by three acts, the effects of which continue to this day. The one which has had the most lasting influence in law is the Statute of Uses, 27 Hen. VIII. c. 10 (see CONVEYANCING; TRUST). The Statute of Uses was intended to provide secrecy of sales of land, and as a necessary sequel to it an act of the same

---

1 Tenants in chief of the crown were liable to a fine on alienation until 12 Car. II. c.
REAL PROPERTY

year (27 Hen. VIII. c. 16) enacted that all bargains and sales of land should be duly enrolled. Bargain and sale was a form of equitable transfer which had for some purposes superseded the common law foemint. It applied only to estates of inheritance and not to terms of years. The unforeseen effect of 27 Hen. VIII. c. 16 was to establish as the ordinary form of conveyance until 1841 the conveyance by lease and release. Uses having become legal estate by the Statute of Uses, and therefore no longer devisible, 32 Hen. VIII. c. 1 (explained by 34 & 35 Hen. VIII. c. 5) was passed to remedy this inconvenience. It is still law as to wills made before 1838 (see WILL). In the reign of Elizabeth the acts of 13 Eliz. c. 5 and 27 Eliz. c. 4 avoided fraudulent conveyances as against all parties and voluntary conveyances as against subsequent purchasers for valuable consideration. Early in the reign of Charles II. the act of 1661 (12 Car. II. c. 24) turned all the feudal tenures (with the exception of frankaldmoign and grand servaity) into tenure by free and common socage and abolished the feudal incidents. The Statute of Frauds (29 Car. II. c. 3) contained provisions that certain leases and assignments, and that all agreements and trusts relating to land, should be in writing (see FRAUD). The land registers of Middlesex and Yorkshire date from the reign of Anne (see LAND REGISTRATION). Devises of land for charitable purposes were forbidden by the Mortmain Act (5 Geo. II. c. 36). In the next reign the first general Inclosure Act was passed 41 Geo. III. c. 109 (see COMMONS). In the reign of William IV. were passed the Prescition, Limitation, and Tithe Commutation Acts; fines and recoveries were abolished and simpler modes of conveyance substituted by 3 & 4 Will. IV. c. 74; and the laws of inheritance and dower were amended by 3 & 4 Will. IV. c. 105, 106. In the reign of Victoria there was a vast mass of legislation dealing with real estate in almost every conceivable aspect. At the immediate beginning of the reign stands the Wills Act. The transfer of real estate was simplified by 8 & 9 Vict. c. 106 and by the Conveyancing Acts of 1881 and 1882. Additional powers of dealing with settled estates were given by the Settled Estates Act 1856, later by the Settled Estates Act 1877, and the Settled Land Act 1882. Succession duty was levied for the first time on freeholds in 1853. The strictness of the Mortmain Act has been relaxed in favour of gifts and sales to public institutions of various kinds, such as schools, parks and museums. The period of limitation was shortened for most purposes from twenty to twelve years by the Real Property Limitation Act 1874. Several acts were passed dealing with the enfranchisement and commutation of copyholds and the preservation of commons and open spaces. The Naturalization Act 1870 enabled aliens to hold and transfer land in England. The Felony Act 1870, abolished forfeiture of real estate on conviction for felony. The Agricultural Holdings Acts 1883 and 1900, and other acts, gave the tenant of a tenancy within the acts a general right to compensation for improvements, substituted a year's notice to quit for the six months' notice previously necessary, enlarged the tenant's right to fixtures, and increased the amount of rent for which the tenant could be removed. The Land Acts of 1884 and 1891, and the Agricultural Holdings Act 1890, extended the law of escheat to incorporeal hereditaments and equitable estates. Among other subjects which have been dealt with by legislation in the 19th century may be mentioned land transfer, registration, mortgage, partition, encumbrance, fixtures, taking of land in execution, declaration of title and apportionment. Hardly a year passes in which the land law is not altered to a greater or less degree.

Real estate at the present day is either legal or equitable, a difference resting mainly upon historical grounds. The following observations apply in general to both kinds of estate. The usual classification of interests in real estate regards either the extent, the time or the mode of enjoyment. The division according to the extent is in the first instance into corporeal and incorporeal hereditaments, a division based upon the Roman law division of res into corporales and incorporales, and open to the same objection, that it is unscientific as co-ordinating subjects of rights with the rights themselves. Corporeal hereditaments, says Blackstone, "consist of such as affect the senses, such as may be seen and handled by the body; incorporeal are not the objects of sensation, cannot be seen, are not subject to the pleasures and pains of the body, and exist only in contemplation." Corporeal hereditaments are all necessarily freehold; an interest in land less than freehold, such as a term of years, is personally only. There was no room for such an interest in the old feudal tenure, and even in the modern tenure of land the existence of estates apart from the land is impossible. An estate in freehold is called a fee simple, generally an obvious sign of its feudal origin. Estates tail are either general or special, the latter being in tail male or (rarely) in tail female. An estate in tail male is a reversion in an estate in frankaldmoign, no. An estate in fee simple is the largest estate known to English law. Its ordinary incidents are an oath of fealty (never exacted), escheat, and (in a manor) suit of the court baron, and occasionally a small quit-rent and relief. All other estates, whether freehold or leasehold, are described as personal. Incorporeal hereditaments consist chiefly, if not wholly, of rights in alieno solo. They are divided by Joshua Williams (Real Property, pt. ii.) into (1) reversions, remainderies and executory interests, (2) estates appurtenant, with their respective divisions according to appurtenance, appurtenant or in gross. Examples are profits a prendre (such as rights of common), easements (such as rights of way), seigniories, adowsons, rents, tithes, titles of honour, offices, franchises. Great care is taken to keep the distinction between incorporeal and corporeal in grant. But by the Real Property Act 1845 all corporeal hereditaments are, as regards the conveyance of the immediate freehold thereof, to be deemed to lie in grant as well as in the Wills Act. The Wills Act gives all personal estates, either in possession or in expectancy—that is, in reversion or remainder or executory interests (see REMAINDER). With regard to the mode of enjoyment, estates are either joint, in common, in tenant in tail, in tenant in fee.

Exceptional Tenures.—It has been already stated that there are still to be found survivals of the old pre-Conquest customary law. They are found both in the tenure and in the conveyance of land. The only customs of which notice may also be a grant by will and succession, see WILL; HERITAGE. Involuntary alienation is by bankruptcy (q.v.) and by other means of enforcing the rights of creditors over land, such as distress or execution. A suit may also arise by the exercise by the state of its right of eminent domain for public purposes, as under the Lands Clauses and other Acts.}

3 From the reign of Edward IV. at latest up to the Fines and Recoveries Act of 1833 fines and recoveries were also recognized as a means of conveyance. They are so regarded in the Statute of Uses.

4 It should be noticed that an easement in gross cannot exist.

5 The right of the state to contribution from land for revenue purposes and to stamp duties on deeds perhaps falls under this head. These impose are really involuntary alienations of part of the profit of the land.
Restraints on Alienation.—The alienation of real estate may be subject to almost any conditions, provided that such conditions do not contravene the law. As a general rule there can be no restrictions upon the alienation of an estate in fee-simple; the two ideas are incompatible. It is not necessary that the conditions under which the estate is to be held or disposed of on the next sale shall be observed, as this restraint on anticipation is allowed within certain limits (see RESTRAINT). In another direction the imposition of a course of devotion upon property is forbidden by the law against perpetuities (see PERSIMMON ACT). Some of the conditions prohibiting the sale of real property are forbidden with a few exceptions. Certain persons are by the general policy of the law disabled from exercising certain proprietary rights, such as convicts, infants and lunatics.

Persons whose rights to real estate are protected by peculiar remedies. At an early period it became more convenient to try the right to the possession of, rather than the right to the property in, real estate. Possessory tended to supersede ownership, and thus the remedies for disputes became simpler. The general mode of trying the right to both property and possession was from the time of Henry II. the real action, the form called "writ of right" (after Magna Carta gradually confined to the court of common pleas) being used to determine the property, that called "assise of novel disseisin" being the general means by which the possession was tried. About the reign of Elizabeth the action of ejectment became the ordinary form of possessory remedy. Real actions are those which relate to the nature or extent of the property in land and are not by the law of possession (inter alia) the redemption or foreclosure of mortgages, the raising of portions or other charges on land, the sale and distribution of the proceeds of property subject to any lien or charge, the specific performance of contracts between vendors and purchasers, the creation of estates, including contracts for leases, the partition or sale of real estates, and the wardship of infants and the care of infants' estates. In the case of rent a summary mode of remedy by act of the creditor still exists (see DISTRESSE, KENT).

Inalienable real estate. Ireland is the English law, which finally superseded the native law in James I.'s reign, as modified by subsequent legislation. The main difference is in the law of landlord and tenant, modified by the various land acts (see IRELAND) and the operation of the Irish Land Commission, by which they were finally abolished, with the exception of writ of right of dower, writ of dower unde nihilo habere, quare impedit and ejectment. Of these quare impedit (q.s.) appears to be the only one now in use. The writ of right of dower, that is, the assise of novel disseisin, the original and its reformed stage, and finally the action for the recovery of land in use since the Judicature Acts are all historically connected as gradual developments of the possessory action. The cases arising from mortgages and the matters of the chancery court of chancellery formerly had exclusive jurisdiction, in most cases because the principles on which the court acted had been the creation of equity. The Judicature Act 1873 assigned the chancery division of the courts of chancery, and created the Court of Chancery for (inter alia) the redemption or foreclosure of mortgages, the raising of portions or other charges on land, the sale and distribution of the proceeds of property subject to any lien or charge, the specific performance of contracts between vendors and purchasers, the creation of estates, including contracts for leases, the partition or sale of real estates, and the wardship of infants and the care of infants' estates. In the case of rent a summary mode of remedy by act of the creditor still exists (see DISTRESSE, KENT).

Inalienable real estate. The law of real estate in the United States is the law of England modified to suit a different state of circumstances. The main point of difference is that in the United States the occupants of land are generally wholly or in part owners, not tenants, and in time is a property of the land rather than a right in the land, as is the case with the English law of mortmain. Perpetuities are forbidden in most states. The right of eminent domain is at once acknowledged and limited by the Constitution of the United States. By art. 5 of the Amendments private property shall not be taken without just compensation.

Domestic Law. The law of the place where real estate is situated (lex loci rei sitae) governs its tenure and transfer. Title of land in England and of the United States are more strict on this point than the laws of most other countries. They require that the formality be performed in the place where the transaction is to be observed in the place where the contract was made. The lex loci rei sitae determines what is to be considered real estate. A foreign court cannot in a general rule pass title to land situated in another country. The English and United States courts of equity have to a certain extent avoided the inconvenience which this inability to deal with land out of the jurisdiction sometimes causes by the use of the theory that equity acts upon the conscience of the party and not upon the title to the foreign land. In the leading case of Penn. v. Lord Baltimore in 1750. (1 Vesey, 444) Lord Baltimore obtained a decree on this ground decried supreme performances in the case of articles settling the boundaries of the provinces of Pennsylvania and Maryland. The difficulty always arises that, although the court procures to act upon the conscience, it must indirectly exercise its jurisdiction to determine the rights of the parties and to carry out its decision without execution of the aid of the local tribunals.

REAPING (either through Du. rieen, or O.F. rayme, reyme, mod. rime, Med. Lat. rima, from Arabic rishah, bake or bundle), a certain quantity of land containing 128 square sheets of 40 square foot each or 480 sheets; a "printer's reel" contains 234 quires or 516 sheets. The word owes its introduction into Europe to the Moors, who were the originators of the paper manufactured in Spain. Its original meaning was simply bundle, applied either to paper or clothes.

Reaping (from O.E. ripan, rypan, probably allied to "ripe," mature, i.e. "fit for reaping"; the cognate forms are found in other languages), the act of cutting ripe grain crops. Till the invention of the reaping machine, which came into practical use only about the middle of the 19th century, sickles and scythes were the sole reaping implements. Of the two the sickle is the more ancient, and indeed there is some reason to conclude that its use is coeval with the cultivation of grain crops. Among the remains of the later Stone period in Great Britain and on the European continent curved flint knives have occasionally been found, the form of which has led to the suggestion that they were reapers. Sickles have been found at the Greeks and among the remains of the early inhabitants of Europe. Some of these are deeply curved hooks, flat on the under side, and with a strengthening ridge or back on the upper surface, while others are small curved knives, in form like the ordinary hedge-bill. Among the ancient Egyptians toothed or serrated sickles of both bronze and iron were used. Ancient Roman drawings show that both the scythe and the sickle were known to that people, and Pliny makes the distinction plain.1 Although both implements have lost much of their importance since the general introduction of mowing and reaping machinery, they are still used very extensively, especially in those countries like France where small agricultural holdings prevail. The principal modern forms are the toothed hook, the scythe hook, the Hainault scythe and the common scythe.

The toothed hook, which was in general use till towards the middle of the 19th century, consisted of a narrow-bladed curved hook, having on one or both sides a series of thin metal strips, somewhat like file teeth, with their edges inclined towards the head or handle. The scythe is that known to mathematicians as the "cissoid," where tangents at any point form equal angles with drawn to the middle of the handle; it has been called the "cure of least exertion" because experience has shown that it tires out the arm of the worker less than any other curve. Sickles were formerly made of iron edged with steel; but in recent times they came to be made of cast steel entirely. Towards the middle of the 19th century the toothed hook was gradually supplanted by the scythe hook or smooth-edged sickle, a somewhat heavier and broader-bladed implement, having an ordinary knife edge. Both these implements were designed for use by one man, with one hand. The Hainault scythe is an implement intermediate between the scythe and the sickle, being worked with one hand, and the motion is entirely a swinging or bagging one. The implement consists of a short scythe blade mounted on a handle and held in the right hand and cut with the tool held in the right. A heavy smooth-edged sickle is used for "bagging" or "clouting,"—an operation in which the hook is struck against the straw, the left hand holding the grass. The common hay scythe is a slight modification of the sickle from 28 to 46 in. mounted on a bent, or sometimes straight, wooden sned or snathe, to which two handles are attached at such distances

1. "Of the sickle there are two varieties, the Italian, which is the shorter and can be handled among brushwood, and the two-handed Gallic sickle, which makes quicker work of it when employed on their [the Gauls'] extensive domains; for there they cut their grass and most of their wood and carry it away with their own hands. The Italian mowers cut with the right hand only." (H. N. xviii. 67)
as enable the workman, with an easy stoop, to swing the scythe blade along the ground, the cutting edge being slightly elevated to keep it clear of the inequalities of the surface. The grain-reaping scythe is similar, but provided with a cradle or short gathering rake attached to the heel and following the direction of the blade for about 12 in. The object of this attachment is to gather the stalks as they are cut and lay them in regular swathes against the line of still-standing corn. The reaping scythe, instead of a long straight blade, has two closely set and slightly curved side-arms, which, in working, are let into the left or right hand branchings of the left or main head and the two handles placed about 2 ft. apart. The best scythe blades are made from rolled sheets of steel, riveted to a back frame of iron, which gives strength and rigidity to the blade. On the continent of Europe it is still common to meld the head of the whole blade out of a single piece of steel, but such scythes are difficult to keep keen of edge. There is a great demand for scythes in Russia, chiefly supplied from the German empire and Austria. The principal manufacturing centre of scythes and sickles in the United Kingdom is Sheffield.

It was not until the beginning of the 19th century that any attempt was made to invent a reaping machine on anything like the lines that have been adopted since. In 1836 the Rev. Patrick Bell of Carnock in Fifeshire brought out the first successful machine. He had worked at the making of it when a youth on his father's farm, and the principle he adopted, that of a series of scissors fastened on the "knife-board," was followed for a long time. There had been many trials during the thirty or forty years before his time both in this country and in America, but his invention was the first practical success.

After many modifications, however, the present or recent form of the common reaper was evolved by C. H. McCormick in America in 1831. A truck or carriage is carried on two travelling wheels some 30 to 36 in. high, with spuds or teeth on the circumference to make them "bite" the ground and thus give motion to the machinery without skidding; two horses are yoked in front with a pole between, with martingale and surcingle belts as part of their harness, to ease the backing of the machine by the horses; the knife-board is fixed out at right angles to the side of the carriage and in front, while the knives consist of a series of triangular "sections" on a bar which travels backwards and forwards in slots in the "fingers," as the dividing teeth are called. The motion was given to the knives by a horizontal crank driven by suitable gearing from the truck wheels. The cutting was thus done by a straight shearing action and not by clipping like scissors as in Bell's machine.

There were many modifications tried before the favourite form was ultimately adopted: thus the horses were yoked behind the truck or carriage of the machine so that they pushed it before them; a revolving web of cloth was placed behind the knives so as to deliver the cut corn in a continuous swath at the side; revolving "sails" or "rakes" pushed the standing grain against the knives as the machine advanced—some of which arrangements have been revived in our modern string-binders—and so on.

In the early days—from about 1860 to 1870—machines were fitted with a tilting board behind the cutting bar which caught the corn as it fell, and it was held there until enough for a sheaf was gathered, when the load was "tilted" off by a suitable rake handled by a man who sat and worked the tilting board simultaneously with his foot and dropped the corn, to be lifted and tied into a sheaf by hand afterwards. The same machine was generally provided with a sacking (rubbing) apparatus, and the "combined" reaper and mower was about the 'seventies and 'eighties. Later, various devices were adopted to do the cutting or shearing mechanically, and the self-delivery and self side-delivery have long been in use whereby through the adoption of revolving rakes on frames the sheaf-lots are delivered in sizes ready for tying up by hand. The subsequent tying or binding was done variously in different parts of the country. In the south of England it was customary for five men to make bands, lift the sheaf-lost, place in the band and tie, and leave the sheaf lying on the ground to be set up afterwards, the gang of five being expected to keep up on a reaper cutting round the four sides of a field. In the north and in Scotland the cutting was only done on one side at a time, the machine riding back empty, and three boys made the bands ("straps"), three women lifted the lots and laid them on the bands, and five men bound the sheaves and set up in stooks. Thus three gangs of three each were required to keep a machine going, and only about five acres per day could be reaped in this way.

Fig. 1.—The Hornsby String-binder.

The development of the modern binder to reduce all this labour has been a very gradual process. There was no great difficulty in cutting the corn and delivering the stuff, but the tying of it into sheaves was the problem to be solved. As early as 1858 Marsh in America designed and carried out an arrangement whereby the cut grain crop was caught on revolving webs of canvas and carried up on to a table, where two men stood and who made bands of its own material and bound it into sheaves as it fell in front of them, dropping the sheaves off on to the ground as made, while the machine travelled along. The invention of a tying apparatus was the next advance, and in the 'seventies the American firm of Walter A. Wood & Co. brought out an arrangement for tying the sheaves up with wire. So slow and expensive had been the process of evolution, however, that it was reported at the time that the above firm had spent £20,000 in invention and experiment before they had even a wire-binder fit to put on the market.

Binding with string, however, was the aim of all, and it was reserved for J. F. Appleby, an English inventor, to hit on the arrangement now in use, or which was the prototype of all the knot- ters now to be met with in different varieties of the string-binder throughout the world.

While the string-binder is now in universal use in Great Britain, the British Colonies, America and all countries where farming and farm work are advanced, and hand labour is only followed where peasant-farming or small farming obtains, it must be noted that in certain regions the system of reaping or harvesting of corn crops has developed a good deal beyond this. In Australia and some of the hotter districts in the west of the United States the "stripper" is in use, an implement which carries long grooved teeth which are passed through the standing grain crop and strip off the heads, leaving the straw standing. The heads are passed backwards to a threshing (rubbing) arrangement, which separates the corn from the chobs, chaff, &c., and the grain is sacked up straight away. The sacks are dropped off the machine as the work proceeds and are picked up by wagon for transport afterwards. It is a significant fact that strippers worked by hand, though pushed through the crop by oxen, were in use on the plains of Gaul in the first
century of our era, though this system seems to have been lost sight of till re-invented by the Australians.

Again, in the Western states of America, where the climate is not hot and dry enough for stripping purposes, the method followed is to cut the straw as short as possible—just below the heads—and these fall on to a travelling canvas and are carried up into a thrasher and the grain separated and sacked as the work proceeds. An immense combined implement is used for this reaping and threshing purpose, taking a width of up to 40 ft. of crop at a time, and being propelled by a 50-horse-power traction engine running on broad roller-wheels, though smaller machines pulled by, say, 20 horses are also common. Sometimes the "heading" only is carried out, and the cut heads carried on a canvas up into a wagon travelled alongside, and then carted away for subsequent threshing; the "header" thus being the form of reaper adopted also in the Western states of America. In these regions, as in many other places on the prairies in general, the straw is of no value, and therefore the whole is set fire to and burned off, thus returning a certain amount of fertility to the soil in the ashes.

The tremendous development in labour-saving in the matter of reaping the corn crops is well exemplified in a comparison of harvesting with the hand hook or sickle as compared with the string-binder. With hand-reaping six men (or women) cut the corn and laid it on the bands in sheaf-lots: one man came behind and tied the sheaves and set them up in stalks. Thus a gang of seven worked together and harvested about two acres per day. With the binder three or four men handle ten or fourteen acres daily: in other words, there is only one-tenth of the manual labour required now in reaping that was necessary only a generation ago, for the string-binder has revolutionized farming as a whole, and given the nations cheap bread.

REAR, the back or hind portion of anything, particularly a military or naval term for that part of a force which is placed last in order, in opposition to "van." As the last word, shortened from "van-guard," is an aphetic form of Fr. avant, in front, Lat. ab ante, so "rear" is an aphetic form of "arrear." O. Fr. arere, mod. arrière, Med. Lat. ad retro, to the back, backward. From this word must be distinguished the verb "to rear," used in two main senses: of a horse, to stand up on its hind legs, and to raise up or lift, of the construction of a building or of the breeding and bringing to maturity of domestic or other animals, often used also of young children. The O.E. vornan, of which it is the modern representative, is a doublet of the Scandinavian reisa, which has given English "raise," both being causative verb forms of "rise."

REAR VAULT (Fr. arrière couchure), the term in architecture employed for the vault of the internal hood of a doorway or window to which a splay has been given on the reveal; sometimes the vaulting surface is terminated by a small rib known as the scouinon rib (g.s.), and a further development is given by angle shafts carrying this rib, known as scouinon shafts.

REASON (Lat. ratio, through French raison), in philosophy, the faculty or process of drawing logical inferences. Thus we speak of man as essentially a rational animal, it being implied that man differs from all other animals in that he can consciously draw inferences from premises. It is, however, exceedingly difficult in this respect to draw an absolute distinction between men and animals, observation of which undoubtedly suggests that the latter have a certain power of making inferences. Between the higher animals and the lower types of mankind the distinction is so hard to draw that many psychologists argue that the difference is one of degree rather than of kind (see also INSTINCT). There can be little doubt, however, that inference by man differs from that of the brute creation in respect of self-consciousness, and, though there can be no doubt that some animals dream, it is difficult to find evidence for the presence of ideal images in the minds of
any but the highest animals. In the nature of the case satisfactory conclusions as to the rationality which may be predicated of animals are impossible.

The term "reason" is also used in several narrower senses. Thus reason is opposed to sensation, perception, feeling, desire, as the faculty (the existence of which is denied by empiricists) by which fundamental truths are intuitively apprehended. These fundamental truths are the causes or "reasons" (ἀρχή) of all derivative facts. With Kant, reason (Vernunft) is the power of synthesizing into unity, by means of comprehensive principles, the concepts provided by the intellect (Verstand). The reason which gives a priori principles Kant calls "Pure Reason" (cf. the Kritik der reinen Vernunft), as distinguished from the "Practical Reason" (praktische Vernunft) which is specially concerned with the performance of particular actions. In formal logic the drawing of inferences (frequently called "ratiocination," from Lat. ratiocinaris, to use the reasoning faculty) is classified from Aristotle downwards as deductive (from generals to particulars) and inductive (from particulars to generals); see LOGIC. Induction, SYLLOGISM. In theology, reason, as distinguished from faith, is the human intelligence exercised upon religious truth whether by way of discovery or by way of explanation. The limits within which the reason may be used have been laid down differently in different churches and periods of thought: on the whole, modern Christianity, especially in the Protestant churches, tends to allow to reason a wide field, reserving, however, as the sphere of faith the ultimate (supernatural) truths of theology.

The Greek words for reason are νοῦς and λόγος, both vaguely used. In Aristotle the λόγος of a thing is its definition, including its formal cause, while the ultimate principles of a science are ἀρχή, the "reasons" (in a common modern sense) which explain all its particular facts. νοῦς in Plato and Aristotle is used both widely for all the meanings which "reason" can have, and strictly for the faculty which apprehends intuitively. Thus, in the Republic, νοῦς is the faculty which apprehends necessary truth, while διάφορα (opinion) is concerned with phenomena.

For the Stoic and Neoplatonic uses of λόγος, as also for those of Philo Judaeus and the Fathers, see LOGOS.

RÉAUMUR, RENÉ ANTOINE FERCHAULT DE (1683-1757). French man of science, was born on the 28th of February 1683 at La Rochelle and received his early education there. He was taught philosophy in the Jesuits' college at Poitiers, and in 1709 went to Bourges to study civil law and mathematics under the charge of an uncle, canon of La Sainte-Chapelle. In 1713 he came to Paris, where he continued the study of mathematics and physics, and in 1708, at the early age of twenty-four, was elected a member of the Académie des Sciences. From this time onwards for nearly half a century hardly a year passed in which the Mémoires de l'Académie did not contain at least one paper by Réaumur. At first his attention was occupied by mathematical studies, especially in geometry. In 1710 he was appointed to the charge of a great government work: the publication of the useful arts and manufactures—which led him to many practical researches that resulted in the establishment of manufactures new to France and the revival of neglected industries. For discoveries regarding iron and steel he was awarded a pension of 12,000 livres; but, being content with his ample private income, he requested that the money should be secured to the Académie des Sciences for the furtherance of experiments on improved industrial processes. In 1731 he became interested in meteorology, and invented the thermometer scale which bears his name. In 1735 family arrangements obliged him to accept the post of commander and intendant of the royal and military order of Saint-Louis; he discharged his duties with scrupulous attention, but declined the emoluments. He took great delight in the systematic study of natural history. His friends often called him the Pliny of the 18th century. He loved retirement and lived much at his country residences, at one of which, La Berneldière (Maine), he met with a fall from horseback, the effects of which proved fatal on the 17th of October 1757. He bequeathed his manuscripts, which filled 138 portfolios, and his natural history collections to the Académie des Sciences.

Réaumur's scientific papers deal with nearly all branches of science; his first, in 1708, was on a general problem in geometry; his last, in 1756, on the forms of birds' nests. He proved experimentally the fact that the strength of a rope is less than the sum of the strengths of its separate strands. He examined and reported on the auriferous rivers, the turquoises, mines, the forests and the fossil beds of France. He devised the method of tinning iron that is still employed, and investigated the differences between iron and steel, correctly showing that the amount of carbon (sulphur in the language of the old chemistry) is greatest in cast iron, less in steel, and least in wrought iron. His book on this subject (1728) was translated into English and German. The thermometer by which he is now best remembered was constructed on the principle of taking the freezing-point of water as 0°, and graduating the tube into degrees each of which was one-thousandth of the volume contained by the bulb and tube up to the zero mark. It was an accident dependent on the dilatability of the particular quality of alcohol employed which made the boiling-point of water 80°; and mercurial thermometers the stems of which are graduated into eighty equal parts between the freezing- and boiling-points of water are not Réaumur thermometers in anything but name.

Réaumur wrote much on natural history. Early in life he described the locomotor system of the Echinodermata, and showed that the supposed vulgar error of Crustaceans replacing their lost limbs was an actual fact. On the point of possibility of spbers being used to produce silk, which was so celebrated at the time that the Chinese emperor Kang-he caused a translation of it to be made. He treated also of botanical and agricultural matters, and devised processes for preserving birds and eggs. He elaborated a system of artificial incubation, and made important observations on the digestion of carnivorous and graminivorous birds. His greatest work is the Mémoires pour servir à l'histoire des insectes, 6 vols., with 267 plates (Amsterdam, 1754-42). It describes the appearance, habits and locality of all the insects except the beetles, and is a marvel of patient and accurate observation. Among other important facts stated in this work are the experiments which enabled Réaumur to prove the correctness of Peysignon's hypothesis, that corals are animals and not plants.

REBAB, or R�ABAB (Persian rubâb; Arabic rabab, rabâba; Sp. rabé, rabâ, rabel, arrabel, arrâbâ; Fr. rubôbe; It. rubebâ), an ancient stringed instrument, having a body either pear-shaped or boat-shaped and the characteristics of vaulted back and the absence of neck; also a generic modern Arabic term applied by the Mahommedans of northern Africa to various stringed instruments played with a bow.

As the rebab exercised a very considerable influence on the history of stringed instruments in Europe, and was undoubtedly the means through which the bow was introduced to the West, it is necessary to examine its construction before deciding whether it may be accepted as the ancestor of the violin in deference to the claim made for it by certain modern writers.

1 The Schoolmen's distinction of ratio cognoscendi (a reason for acknowledging a fact) and ratio essendi (a reason for the existence of this fact).

2 F. Rückert, Grammatik, Poetik und Rhetorik der Perser, nach der kürzesten Regel der Geschichte (1840), p. 80. This translation of the introduction to the Seven Seas contains a reference to musical instruments; the one translated Laute (lute) is rendered in Persian rubâb, a point ascertained through the conscientious assistance of Mr. A. G. Ellis, of the Oriental Department, British Museum.

5 See F. J. Fétis, Antoine Stradiotire ... Précédé de recherches historiques et critiques sur l'origine et les transformations des instru-
The two principal forms of rebab with which we are concerned as prototypes of European instruments of the middle ages are:

1. The long and narrow boat-shaped rebab, which may be traced back to Persia in the 8th century B.C., and is still in use in that country; and
2. The short and broad boat-shaped instrument of the 12th century, consisting of the gradual narrowing of the body, which has the outline of a longitudinal section of a pear. This variety became very popular in medieval Europe under the names of rebec, gigue, ginek, and rebab. The rebab (fig. 1), which was used as an instrument in the 11th century, has the most characteristic feature in the construction of the rebab, and of all instruments derived from it, was the body, composed of a back originally scooped out of a solid piece of wood, to which was added the soundboard with the strings. The rebab-esh-sha'er, or "poet's rebab," had a body consisting of an almost rectangular box covered with parchment and supported by strings. A second lower string was inserted when it was played as a viol or viola. The rebab was also used as a snare drum (see also GUITAR AND GUITAR-FIDDLE). Instruments of this type were at all times recognized as superior to the viol in size and in its construction, and were played in the same way. Of the rebab, one of the chief characteristics was its use for the development of the violin and in the time when the first type had nearly reached its apogee, the second was placed beyond the pale of art. According to Al-Farabi, the rebab had either one string or two, depending on the number of cuts which they were made in the wood. This is mentioned in the manual of the Persian M. Flinders Petrie during the course of excavations in the cemetery of Goshen, 4 Greek work of the post-Mycenaean age; it was

found in surroundings assigned to the XXth Dynasty (c. 1000 B.C.), and shows the earliest pear-shaped instrument yet discovered. This statuette clearly establishes the instruments of the present day with the exception of the rebab. The instrument is described in the Hellenistic period of the 11th century, whose main characteristic is an almost entire absence of neck. Two terra-cotta statuettes of musicians playing upon ancient Persian rebabs (see fig. 2) have been excavated from the

Tell at Susa among objects referred to the reign of Shutruk-Nakhouma, who was king of Elam c. 789 B.C. The pear-shaped instrument, wide at the base and elongated to form a neck, with the head bent back at right angles and the strings plucked by the fingers,—the lute of the 6th century A.D.,—is seen first on a frieze from Afghanistan, forming one of the risers of steps to the temple of Jama-Garhi. These sculptures, preserved at the British Museum, are assigned to the 2nd or 3rd century, and are said to show traces of classical influence. The same instrument is found engraved on a Sassanian silver dish in the British Museum, which workmanship assigned to a period not later than the 7th century A.D., but probably earlier, as well as on other dishes of similar origin; one in the Hermitage, St. Petersburg, was found at Irbit in 1880, on which Eros is depicted playing the lute and riding on a lion. A third, found at Persepolis, is part of Count Stroganov's collection.

Excavations carried out in ancient Khotan or Ichir (Turkestan, on the caravan route to Kashgar) have brought light further evidence of the ubiquity of the rebab type in Asia. In addition to the two principal types of rebab (fig. 3) mentioned above there were also found one spout-shaped instrument with no neck and a large round head (fig. 4), sometimes seen in European medieval sculptures and MSS. of the 11th and 12th centuries. The pear-shaped rebab or lute appears also among the decorated panels in the Buddhist cave temples of Ajanta. 8

REBATE—REBEC

REBEC, or REBECK (Med. Fr. rubèbe, rebelle, rebec, gigue; Ger. Rubeba, Rebek, Geige, Lyra; Ital. ribeba, ribeca, lyra; Sp. rebeca, rebeca, rebeca; Lus. rebeca, rebeca). An angular instrument played with a bow, derived from the Oriental rebab. Like the rebab (q.v.), the rebec assumed at first one of two forms—the pear-shaped body with a wide base, strung with three strings, or the long, narrow pear- or boat-shaped body with two strings, and, in addition, the other Oriental characteristics of the rebab, i.e. the vaulted back, the absence of ribs and pegs set in the back of the head. Except for the addition of a fingerboard, what is now recognised as the rebec underwent no structural development and never entered the domain of art. When the guitar-fiddle and the oval vielle with five strings made their appearance in Europe, apparently during the 11th century, a number of hybrids combining characteristics of both types of construction spread rapidly over western Europe.

A spoon-shaped instrument, in most cases without neck, the head being joined directly to the wide shoulders of the body, must not be confounded with these hybrids; the compass and capabilities of the instrument, which sometimes had but one single string, must have been extremely limited. What the name of the instrument was in the various ages is not known, rebab is the modern Arabic name for it, with which it only differs in the outline of the body. The present writer discovered an Oriental archetype on a small terra-cotta figure in the style of the Gandhāra school, unearthed at Yōtākan on the site of the ancient Khotan. The round head is fastened directly to the shoulders, the three strings are thrown into relief by deep indentations, the bridge tail-piece has three notches. The instrument (assigned to some period between the 5th and 8th centuries A.D.) may be compared with the European medieval type, such, for instance, as the bowed spoon-shaped rebec on the capital of the left pillar in the miniature of King David and his musicians, belonging to the 10th-century psalter of Labo Notker at St Gallen; also with the musicians' lyra on the western doorway of the church at Moissans; and with the British Museum Add. MS. 17333, in which several of these spoon-shaped, neckless instruments are to be found.

The pear-shaped rebec with wide base was in all probability introduced into Europe through the Byzantine Empire, and the narrow boat-shaped by the Moors by way of Spain. The first of these types is represented on one of the sides of an ivory casket of Italo-Byzantine work of the 8th or 9th century, belonging to the Carrard Collection in the Palazzo del Podesta in Florence. It belongs to the same group as the Veroli casket at the South Kensington Museum, all of which are assigned to the 9th century at the latest.

The spoon-shaped rebec, although like all rebecs it had no separate neck, was elongated to form one, and terminated in a lozenge-shaped head all in one piece with back and neck, the soundboard being cut to the same outline and glued to the back. There were still two pegs, but one string and resembles the lyra teutonica mentioned above.2

Medieval documentary evidence points to the fact that the long boat-shaped rebec had survived in Spain and spread by way of France over western Europe. The much-quoted 14th-century

REBEC, or REBECK (Med. Fr. rubèbe, rebelle, rebec, gigue; Ger. Rubeba, Rebek, Geige, Lyra; Ital. ribeba, ribeca, lyra; Sp. rebeca, rebeca, rebeca; Lus. rebeca, rebeca). An angular instrument played with a bow, derived from the Oriental rebab. Like the rebab (q.v.), the rebec assumed at first one of two forms—the pear-shaped body with a wide base, strung with three strings, or the long, narrow pear- or boat-shaped body with two strings, and, in addition, the other Oriental characteristics of the rebab, i.e. the vaulted back, the absence of ribs and pegs set in the back of the head. Except for the addition of a fingerboard, what is now recognised as the rebec underwent no structural development and never entered the domain of art. When the guitar-fiddle and the oval vielle with five strings made their appearance in Europe, apparently during the 11th century, a number of hybrids combining characteristics of both types of construction spread rapidly over western Europe.

A spoon-shaped instrument, in most cases without neck, the head being joined directly to the wide shoulders of the body, must not be confounded with these hybrids; the compass and capabilities of the instrument, which sometimes had but one single string, must have been extremely limited. What the name of the instrument was in the various ages is not known, rebab is the modern Arabic name for it, with which it only differs in the outline of the body. The present writer discovered an Oriental archetype on a small terra-cotta figure

1901), vol. i. pl. xiv. No. 311.1d.

3 See Laurent Grillet, Les ancêtres du violon (Paris, 1901), vol. i. p. 29. The author calls these instruments lyra, which is a synonym of rebab.

5 A rebec string has been identified by A. Veh in a gallery of the Vatican (L’art, vol. iii., 1897, p. 265; and L’Arte, vol. i. 1896, p. 24.

6 See also English psalters of the 13th century in the British Museum. Lansd. MS., 420, and Arundel, 157, fol. 718.

poem by Juan Ruiz, archipreste de Hita, containing an enumeration of the musical instruments of his day, includes el rebec gritero (the shrill rebec with its high note) and el rebec morisco. By a process of deduction we have no difficulty in identifying the boat-shaped rebec with the instrument mentioned in the magnificent MS. known as the Cantigas de Santa Maria, assigned to the 13th century, where there are three of those boat-shaped rebecs played with a bow and one twanged by the fingers; they have handles (the string is not stretched across the violin-type of the rebec of this type, but without bows, were in use in ancient Persia, c. 789 B.C., as is demonstrated by some little terra-cotta figures of musicians unearthed in a tomb at Susa. Two of the instrument were held, however, like the violin, the unmistakably the archetype of the rebec.

The rebec did not escape the general tendency so noticeable in Europe from the 12th to the 15th century towards the ornamentation of musical instruments with grotesque heads. The cittern of the chansons de geste, the heads of the cittern and lutes, the mandoline and the rebec, were all alike decorated with grotesque human or animal heads, which in England became proverbial as cittern-heads.

The boat-shaped rebec survived as the sorabino or pochette, an instrument widely used by dancing masters until the 19th century, when it was abandoned for the kit, a diminutive violin. The pochette, as its name in French and also in German (Taschengeige) indicates, is a rebec with a more slender form, of which less than 15 to 18 inches long and with a correspondingly small bowl. The 15th- and 16th-century rebec or geige, as the pear-shaped variety was called in Germany (geige in France), is figured by Sebastian Virdung in his Musica Getreue (1511). The Arab rebec was also described by G. Capriani, a finger-board cut in one piece with the sound-board in some cases and forming a step. Some writers consider that the addition of the finger-board constituted the difference between the geige and the rebec, the former being a stronger instrument. In Italy, however, the rebec in the 9th or 11th century already had a finger-board, and Farabi, the Arabic scholar of the 10th century, who was equally familiar with the Greek, Persian and Arabic musical systems, distinctly states that the rebec was a kind of lyra. The Greek rebec with three strings is to this day played by rustic musicians under the name of lyra. Moreover, in Germany, bowed instruments of all kinds were at first known as geige, in contradistinction to those whose strings were plucked, classed together as cythara or some word derived from it, the most modern example of which is the zither. With the rise of the viol and later of the violin, which represent the most perfect type of construction for stringsed instruments, the rebec tribe, inferior in every respect and without artistic merit, was gradually relegated beyond the pale, and by the 18th century had fallen into disuse except in certain rural districts, where for outdoor music, their shrill, penetrating tone continues to endear them to itinerant and village musicians.

3. For an illustration see Carl Engel, Researches into the History of the Violin Family, and E. Heron-Allen, The Violin, and how to maintain it.
4. Edward Ehube is of opinion that the miniatures in these MSS. are the work of a 14th-century artist. See Die Musikinstrumente in den Miniaturhandschriften des Mittelalters (Leipzig, 1903).
5. See J. de Morgan, La Délégation en Perse (Paris, 1900), vol. i, pl. viii, Nos. 8 and 9.
6. There is a pochette in the Galpin Collection, c. 1700; for an illustration see Kathleen Schlesinger, The Instruments of the Orchestral Family, pp. 60-61.
8. Antoine Vital in La Lutherie et les luthiers, to show the contempt with which the rebec was held. The rebec described by Vital in 1778 as "an instrument of no value" is in line 1249 of the "Supplet," and the following entries occur: "On donna sur son ordre 35 sols à une poive insensée qui jouoit du rebec." The lieutenant of Paris, in March 27, 1757, following order that "faisant défense à tous musiciens de jouer dans les cabarets et mauvais lieux des danses basses ou autres parties de violon ainsie seulement du rebec." A well-known passage in Chaucer testifies to a similar contempt in 14th-century England: "Brother, quod he, here wone an old rebelke." Ec. (Penes Tales, 1716).

REBECCA RIOTS—REBUS

REBECCA RIOTS, the name given to some disturbances which occurred in 1843 in the counties of Pembroke, Carmarthen, Glamorgan, Cardigan and Radnor, after a slight outbreak of the same nature four years previously. During a period of exceptional distress the rioting was caused mainly by the heavy charges at the toll-gates on the public roads in South Wales, and the rioters took as their motto the words in Genesis xxiv. 60. "And they blessed Rebekah, and said unto her, Thou art our sister, be thou the mother of thousands of millions, and let thy seed possess the gate of those who hate thee." Many of the rioters were disguised as women and were on horseback; each band was led by a captain called "Rebecca," his followers being known as "her daughters." They destroyed not only the gates but also the toll-houses, and the work was carried out suddenly and at night, but usually without violence to the toll-keepers, who were allowed to depart with their belongings. Emboldened by success, a large band of rioters marched to the town of Carmarthen on the 3rd of June and attacked the workhouse, but on this occasion they were dispersed by a troop of cavalry which had hurried from Cardiff. The Rebeccaites soon became more violent and dangerous. They turned their attention to other grievances, real or fancied, connected with the system of landholding, the administration of justice and other matters, and a state of terrorism quickly prevailed in the district. Under these circumstances the government despatched a large number of soldiers and a strong body of London police to South Wales, and the disorder was soon at an end. In October a commission was sent down to inquire into the causes of the riots. It was found that the grievances had a genuine basis; measures of relief were introduced, and South Wales was relieved from the burden of toll-gates, while the few rioters who were captured were only lightly punished.

REBELLION, the act or continuance in act of a rebel or rebels (Lat. rebellia, rebels, a compound of re-, against, and bellum, war). A rebel is one who engages in armed resistance to the government to which he owes allegiance. For the distinction between Civil War and Rebellion, see WAR, LAW OF. Where individuals as distinguished from groups of men are concerned the character of rebel is easier to determine. That the alleged act of war was done by order of another cannot be in principle an excuse for a subject or citizen of any state taking arms against it. Under the rules of war adopted at the Hague in 1907, moreover, any excuse for doing so is removed by the provision that a belligerent is forbidden to compel nationals of the hostile party to take part in operations of war against their own country, "even if they were in the belligerent's service before the commencement of the war" (art. 132). In the case of R. v. Lowe, known as the "Calvinia Flogging case" (Supreme Court of the Cape Colony, Feb. 18, 1904), the question of the validity of the excuse of acting under orders received in the course of war was discussed in an unpublished opinion, and in a previous case, the Moritz case, tried before the Treason Court at Mafeking (Nov. 7, 1901), the court held that insurgent nationals "who had joined theburgers must be placed on the same footing as burghers fighting against us." There may be special circumstances operating to qualify the application of a principle, but the above stated principle, as such, must be regarded as the only legal basis of argument on the subject.

(T. B. A.)

REBUS (Lat. rebus, "by things"), a sort of riddle consisting of the representation of some sentence or thing by means of pictures or words, or a combination of both. Rebus first became popular in France, where they were at first called rebus de Picardie, that province, according to G. Ménage (1613-1629), having been the scene of their origin, which he found in the satires written by the students and young clerks on the foibles of the day under the title De rebus quae germinant. Camden mentions an instance of this kind of wit in a gallant who expounded his lines to his lady: "The border of his gown a rose, a hill, an eye, a loaf and a well; this, in the style of the rebus, reads "Rose Hill I love well." This kind of wit was happily ridiculed by Ben Jonson in the humorous description of Abel Druggar's device in the Alchemist and by
the Spectator in the device of Jack of Newbery. The name is also applied to arrangements of words in which the position of the several vocables is to be taken into account in divining the meaning. Thus "I understand you undertake to overthrow my undertaking" makes the rebus stand take to taking you throw my;

or in French

pir vent venir un vient d’un

may be read "un soupir vient souvent d’un souvenir." A still simpler French rebus is expressed by the two letters G a, which may be read, J’ai grand appétit (G grand, a petit). "Rebus" (or "allusive arms"), in heraldry, is a coat of arms which bears an allusion to the name of the person,—as three castles for Castleton, three cups for Butler, three cones for Coningsby.

RÉCAMIER, JEANNE FRANÇOISE JULIE ADÉLAÏDE (1777–1849), a famous Frenchwoman in the literary and political circles of the early 19th century, was born on the 4th of December 1777 at Lyons. Her maiden name was Bernard. She was married at fifteen to the banker Jacques Récamier (d. 1830), who was more than old enough to be her father. Beautiful, accomplished, with a real love for literature, she possessed at the same time a temperament which protected her from scandal, and from the early days of the consulate to almost the end of the July monarchy her salon in Paris was one of the chief resorts of literary and political society that pretended to fashion. The habitués of her house included many former royalists, with others, such as Bernadotte and General Moreau, more or less disaffected to the government. This circumstance, together with her refusal to act as lady-in-waiting to the Empress Josephine and her friendship for Madame de Staël, brought her under suspicion. It was through Madame de Staël that Madame Récamier became acquainted with Benjamin Constant, whose singular political tergiversations during the last days of the empire and the first of the restoration have been attributed to her persuasions. Madame Récamier was eventually exiled from Paris by Napoléon’s orders. After a short stay at Lyons she proceeded to Rome, and finally to Naples, where she was on exceedingly good terms with Murat and his wife, who were then intriguing with the Bourbons. She persuaded Constant to plead the claims of Murat in a memorandum addressed to the congress of Vienna, and also induced him to take up a decided attitude in opposition to Napoléon during the Hundred Days. Her husband had sustained heavy losses in 1805, and she visited Madame de Staël at Coppet in Switzerland. There was a project for her divorce, in order that she might marry Prince Augustus of Prussia, but though her husband was willing it was not arranged. In her later days she lost most of the rest of her fortune; but she continued to receive visitors at the Abbaye-aux-Bois, the old Paris convent to which she retired in 1814. Here Chateaubriand was a constant visitor, and in a manner master of the house; but even in old age, ill-health and reduced circumstances Madame Récamier never lost her attraction. She seems to have been incapable of any serious attachment, and although she numbered among her admirers Mathieu de Montmorency, Lucien Bonaparte, Prince Augustus of Prussia, Ballanche, J. J. Ampère and Constant, none of them obtained over her so great an influence as did Chateaubriand, though she suffered much from his imperious temper. If she had any genuine affection, it seems to have been for Prosper de Barante, whom she met at Coppet. She died in Paris on the 11th of May 1849.

There are well-known portraits of her by Louis David in the galleries of the Louvre, and by François Gérard in the possession of the préfet of the Seine. In 1859 Souvenirs et correspondances tirés des papiers de Madame Récamier was edited by Mme Lenormant. See Mme Lenormant’s Madame Récamier, les amis de sa jeunesse et sa correspondance intime (1872); Mme Mohl, Madame Récamier, with a sketch of the history of society in France (1829 and 1862); also Guizot in the Revue des deux mondes for December 1859 and February 1873; H. Noel Williams, Madame Récamier and her Friends (London, 1901); E. Herriot (Engl. trans., by Alyx Hallard), Madame Récamier et ses amis (1904) (elaborate and exhaustive).

RECANATI, a city of the Marches, Italy, in the province of Macerata, 8 m. direct N.N.E. of the city of that name. Pop. (1801) 14,590 (town), 16,380 (commune). It has a station on the railway 173 m. of Ancona, and distant 4½ m. from the town, which is built on a hill, 931 ft. above the sea, and retains portions of its 15th-century walls and gateways. It was the birthplace of the poet Leopardi (1798–1837), whose monument adorns the principal piazza and whose family has collected in the town a very interesting museum of Leopardiana; it also contains fine old mansions of the Leopardi, Mazzagalli, Massucci and Carradori in the main street, and a Gothic cathedral, built towards the close of the 14th century and dedicated to St Flavianus, patriarch of Constantinople. The churches of S Maria sopra Mercanti and San Domenico contain characteristic examples of the work of Lorenzo Lotto, as also does the new municipal palace, with a fine front embellished by lower, while the palace of Cardinal Venier has a fine Renaissance loggia by Giuliano da Maiano, who was probably responsible for the designs for the portals of S Agostino and S Domenico. The older buildings of the town are noteworthy for the curious terra-cotta work which adorns the majority of them.

Recanati appears as a strong castle in the 10th century or earlier. Round this gathered a community whose petty wars with Osimo (Auximum) called for the interference of Innocent III. in 1198. From Frederick II. it obtained the right of having a port on the Adriatic; and by Gregory IX. it was made a city and the seat of the bishopric transferred from Osimo. This oscillation between Guelf and Ghibelline continued characteristic of Recanati. Urban IV. abolished the "city" and bishopric; Nicholas IV. restored them. John XXII. again, in 1320, removed the bishopric and placed the city under interdict. The interdict was withdrawn in 1328 on payment of a heavy fine, but the bishopric remained in abeyance till 1357. Gregory XII. who on his deposition by the council of Constance was made papallegate of the sees of Macerata and Recanati, died in this city in 1417. The assistance rendered by the pope to the popes in their struggles with the Sforza seems to have exhausted its resources, and it began to decline. Considerable damage was done by the earthquake of 1741; and the French, who were twice in possession of the city in 1797, pillaged it in 1799.

RECEIPT (M.E. receite, derived through Fr. from Lat. recepta, participle of recipere, to receive), in law, an acknowledgment in writing that a sum of money or other valuable considered has been received by the person signing the acknowledgment in discharge of a debt or other obligation. Such a receipt is prima facie evidence only of payment, and it may be shown, for example, that it was signed by mistake, or obtained by fraud or misrepresentation. By the Stamp Act of 1801, which repealed and re-enacted other acts, a duty of 1d. is imposed on every receipt or form of writing discharging a debt of £2 or upwards; the payment of the duty is denoted by affixing a penny stamp to the document, and the cancelling of the same by the person giving the receipt. By § 103 if a person gives a receipt, liable to duty, not duly stamped, or refuses to give a receipt, liable to duty, duly stamped or not, or refuses to pay the amount of £2 or upwards, the receiver is liable for a fine of £2. The amount paid with intent to evade the duty, he is liable to a fine of £10. A receipt not duly stamped may be stamped at the Inland Revenue Office within fourteen days on payment of a fine of £5 or within one month on payment of £10.

RECEIVER, in English law, an officer or manager appointed by a court to administer property for its protection, to receive rent or other income and to pay authorized outgoings. Receivers may be either appointed pendente lite or by way of equitable execution, e.g. for the purpose of enabling a judgment creditor to obtain payment of his debt, when the position of the real estate is such that ordinary execution will not reach it. Formerly receivers were appointed only by the court of chancery, but by the Judicature Act 1873 it is now within the power of all
RECEPT—RECHBERG-ROTHENLOWEN

Later references to them probably indicate that the term was used by the ancients merely as a name (Kesew., H. E. ii. 23), the particular form of asceticism (q.v.) being less essential. One may compare the modern society of total abstainers known as the "Rechabites." In 1 Chron. ii. 55 the "house of Rechab" is associated with the Kenites (q.v.) as a family of scribes. Their origin is ascribed to Hammah (conceivably the Naphthali city, Josh. xiii. 35), but in 1 Chron. iv. 12 Rechab (so the LXX) is of Calebite descent.

RECHBERG-ROTHENLOWEN, JOHANN BERNHARD, Count (1806-1899), Austrian statesman, was the second son of the Bavarian statesman Count Aloys von Rechberg-Rothenlöwen (1766-1849). Johann Bernhard was destined for the Bavarian public service, his elder brother being a hereditary member of the Upper House in the parliament of Württemberg. He was educated at the universities of Strassburg and Munich, but he incurred the displeasure of King Louis I. by the part he played as second in a duel, and in 1828 he transferred himself to the Austrian diplomatic service. After being attached to the embassies in Berlin, London and Brussels, he was appointed envoy at Stockholm (1844) and at Rio de Janeiro (1843). Returning to Europe in 1847, on the outbreak of the revolution in Vienna he was great service to Prince Metternich, whom he accompanied and assisted in his flight to England. In July 1848 he was appointed Austrian plenipotentiary in the German federal diet at Frankfort, in 1851 became Austrian internuncio at Constantinople, and in 1853 Radetzky's civilian colleague in the government of Lombardo-Venetia. In 1855 he returned to Frankfort as Austrian representative and president of the federal diet. As a pupil of Metternich he would have wished to preserve the good understanding with Prussia which seemed the necessary foundation for a conservative policy; he was, however, made the instrument for the anti-Prussian policy of Buol; this brought about constant disputes with Bismarck, at that time Prussian envoy at the diet, which were sharpened by Rechberg’s choleric temper, and on one occasion led him to express a high appreciation of his character and abilities. In May 1859, on the eve of the war with Italy, he was appointed Austrian minister of foreign affairs and minister president, surrendering the latter post to the archduke Rainer in the following year.

The five years during which Rechberg held the portfolio of foreign affairs covered the war with Italy and France, the insurrection in Poland, the attempted reform of the German Confederation through the Frankfort Fürstenstag, and the Austro-Prussian war with Denmark. After the defeat of Magenta Rechberg accompanied the emperor to Italy, and he had to meet the crisis caused by a war for which he was not responsible. He began the concessions to Hungary and in the Polish question, and was responsible for the adhesion of Austria to the alliance of the Western Powers. In the German question Rechberg’s policy was one of compromise. To the project of the Fürstenstag he was altogether opposed. The project had been suggested to the emperor Francis Joseph by his son-in-law, the hereditary prince of Turn and Taxis, and by a pamphlet of Julius Fröbel, and the preliminary arrangements were made without Rechberg being informed. When at last he was told, he tendered his resignation, which was not accepted, and he accompanied the emperor to the abortive meeting at Frankfort (August 1863). The attempt made by Rechberg at the subsequent ministerial conference at Nuremberg to establish a German league without Prussia was equally unsuccessful, and he now left the policy, which in opposition to Schmerling he had throughout advocated, of a peaceful arrangement between Prussia and Austria as the indispensable preliminary to a reform of the Confederation.

At this juncture the death of King Frederick VII. of Denmark (15th of November 1863) opened up the whole Schleswig-Holstein question (q.v.). In the diplomatic duel that followed Rechberg was no match for Bismarck. It suited Austrian policy to act in concert with Prussia against Denmark; but Rechberg well knew that Bismarck was aiming at the annexation of the duchies. He attempted to guard against this by laying
RECIDIVISM—RECIFE

down as a condition of the alliance that the duchies should only be separated from Denmark by common consent of the two German powers. Bismarck, however, insisted that the question of the ultimate destination of the duchies should be left open; and, when he backed his argument with the threat that unless Austria accepted his proposal Prussia would act alone, Rechberg gave way. His action was made the object of violent attacks in the Austrian Lower House (28–30 January 1864), and when the war was victoriously concluded and Prussia's designs on the duchies had become evident, public opinion turned more and more against him, demanding that Austria should support the duke of Augustenburg even at the risk of war. Rechberg yielded so far as to assure the duke's representative at Vienna that Austria was determined to place him in possession of the duchies, but only on condition that he did not sign away any of his sovereign rights to Prussia. The outcome of this was that the duke refused the terms offered by King William and Bismarck.

On the 22nd of August there was a meeting of the emperor Francis Joseph and King William at Schönbrunn, both Rechberg and Bismarck being present. Rechberg himself was in favor of a peace treaty that would allow Francis Joseph to take possession of what was once his, and that Prussia should guarantee Austria's possession of Venice and the Adriatic coast. On the first point no agreement was reached; but the principles of an Austro-Prussian alliance in the event of a French invasion of Italy were agreed upon. This latter proposal was, however, received with violent opposition in the ministry, where Rechberg's influence had long been overshadowed by that of Schmerling; public opinion, utterly distrustful of Prussian promises, was also greatly excited; and on the 27th of October Rechberg handed in his resignation, receiving at the same time the order of the Golden Fleece from the emperor as a sign of special favour. He had been made an hereditary member of the Upper House of the Reichsrat in 1861, and as late as 1879 continued occasionally to take part in debates. He died at his château of Kettenhof near Vienna on the 26th of February 1899. He had married, in 1834, Barbara Jones, eldest daughter of the 6th Viscount Ranelagh, by whom he had one son, Count Louis (b. 1839).

See the biography by Franz Ilwoph in Allgemeine Deutsche Biographie, B. 53. Nachträge (Leipzig, 1907).

RECIDIVISM (from Fr. récidiver, to relapse and fall again into the same fault, or repeat the same offence as one committed before), a modern expression for "habitual crime." The recidivist is now universally known to exist in all civilized countries as one who has adopted wrong-doing and law-breaking as a profession. His persistency is ceaseless and inextinguishable by the ordinary methods of combating crime. Penal justice as generally exercised is unavailing, and is little better than an automatic machine which draws in a vast number within its wheels and casts them out again practically unchanged in character to qualify again for the ineffective treatment. This dangerous contingent is for ever on the move, into prison and out of it and in again; a large proportion of it, the criminal residuum, the very essence of the criminality of a country, resists all processes devised for its regeneration and cure. Nothing will mend it; neither severity nor kindness, neither the most irksome restraints nor the philanthropic methods of moral and educational persuasion. This failure has encouraged some ardent reformers to recommend the system of indefinite imprisonment or the indeterminate sentence, by which the enemy once caught is kept perpetually on condition, and thus rendered innocuous. Habitual offenders, it is argued, should be detained as hostages until they are willing to lay down their arms and consent to make no further attempt to attack or injure society. The theory is sound and has been adopted in part in several countries, especially in the United States.

It was not until 1909 that the system of preventive detention was put into operation in the United Kingdom, when, by the Prevention of Crime Act 1908, power was given to the courts to pass on habitual criminals a sentence of preventive detention in addition to one of penal servitude. This further period may range within limits of from five to ten years, according to the discretion of the court. The English system is hardly more than tentative at present; the machinery is admittedly capable of improvement. The charge of being an habitual criminal has to be inserted in the indictment on which the offender is to be tried, and this cannot be done without the consent of the director of public prosecutions and after certain notice has been given to the officer of the court trying the prisoner and to the offender himself. The decision to charge a prisoner with being an habitual criminal has hitherto rested on the local police authorities, and it has been felt that a more even and a more general application of such a drastic method of treatment would result if the decision were transferred to one authority, and some such reform was foreshadowed by the Home Secretary in a speech in the House of Commons on prison reform on the 20th of July 1910.

RECIFE, or PERNAMBUCO, a city and seaport of Brazil, capital of the state of Pernambuco, in 8° 3' S. and 34° 55' W., near the extreme eastern point of South America. Pop. (1904 estimate) 186,000. Recife is frequently called the "Venice of America," or it is the mouth of the rivers Beberibe and Capibaribe which unite to form a small bay, the Bahia de Recife, which opens to the sea. In the angle between the two rivers is the delta island of Antonio Vaz. The city is built on the southern extremity of the sandy sea beach, on the island of Antonio Vaz, and on the mainland to the westward, the river channels being crossed by numerous bridges. With the exception of the hills on which Olinda is built about 5 m. northward, the surrounding country is low and flat, the general elevation averaging 10 ft. As the tide rises about 6 ft., the general level of the city and neighbouring coast, which is wet and swampy to the southward, is too low to be generally healthy, and Pernambuco has a high death-rate (52 per 1000 in 1904), with malaria as one of the principal causes of death. The climate is hot, although agreeably tempered by the S.E. trade winds; the temperature ranges from an absolute minimum of 61° to an absolute maximum of 90° (1904). The rainfall (1904) is 75-3 in. The three principal parishes of the city are known as São José do Recife, occupying the sandy peninsula or beach north of the outlet of the united rivers; Santo Antonio, on the island of Antonio Vaz, between Capibaribe and the river Beberibe; and Boa Vista in the mainland of the island of Mauritius during the Dutch occupation; and Boa Vista is considered as the most modern and the most rapidly growing part. The first is the oldest and most crowded section, and is now devoted chiefly to the commercial and financial interests of the port; here are the custom house, merchants' exchange (Fracá do Commercio), shipping offices, banks and wholesale houses. Santo Antonio dates from the Dutch occupation. Prince Maurice of Nassau, when governor-general, built here his private residence (Fribourg House) and made it his capital. Its business edifices and residences are largely of Dutch architecture, with many stores and steep roofs. The older part of Boa Vista dates from the 17th century. Recife has few public squares or gardens, and its streets are not usually well cared for. The older buildings are of the Portuguese type, usually plain, low and heavy, constructed of broken stone and mortar, and plastered and coloured on the outside. The city has gas and electric illumination, street and suburban railways, drainage and a public water supply drawn from a small tributary of the Beberibe about 7 m. to the N.W., in the direction of Caçangá. Among its notable public buildings and institutions are the old municipal palace in Santo Antonio built upon the foundation of the official residence of Prince Maurice of Nassau, with a pretty garden attached; a theatre facing upon the Praça da Republica, dating from the second empire; the palace of the Provincial Assembly in Boa Vista, built in 1866–66, surmounted by a high dome; the municipal palace, or prefecture, on Rua do Imperador, with the public library (Biblioteca Publica) occupying its third floor and containing about 30,000 volumes; the Gymnasium, a large plain building of two floors standing near the legislative palace; the Pedro II. hospital
But in the United States reciprocity is the term applied to the concessions or arrangements made between that country and another without reference to any third country. Thus in the United States there are a maximum and minimum tariff, the rates of the maximum tariff being enforced on the goods of those countries which have no reciprocity treaty with the United States, and the rates of the minimum on certain products of those countries which have by a reciprocity treaty given special advantages or concessions to certain products of the United States.

RECLAMATION (from Lat. reccitare, to read out, particularly of a public document), an account or repetition of the details of some act, proceeding, fact, &c., particularly, in law, that part of a legal document, such as a lease, which contains a statement of certain facts, e.g., the purport for which the deed is made. In music, the word is used of an instrumental performance given by a single person, and also of a performance of the works of a single composer.

WECKLINGHAUSEN, a town of Germany, in the Prussian province of Westphalia, 22 m. by rail N.W. of Dortmund on the railway to Münster. Pop. (1905) 44,396. In the neighbourhood are extensive coal-mines and brick-works, and the industries embrace the manufacture of linen, beer, spirits and tobacco.

The county of Recklinghausen belonged to the archbishopric of Cologne until 1803, when it passed to the duke of Arenberg. It was known as the Vest Recklinghausen. In 1810 it was divided by Napoleon between the grand duchy of Berg and France, but was, in 1815, restored to the duke of Arenberg as a fief under Prussian sovereignty.

See Ritz, *Die ältere Geschichte des Veste und der Stadt Recklinghausen* (Erzen, 1904).

RECLAMATION OF LAND. The boundaries between sea and land are perennally changing. In many sheltered bays and estuaries the land is receding, while along other portions of the sea-coast it is continuously encroaching. The same causes operate to produce both results: the rivers carry down with them detritus and sediment from the higher ground; the sea, aided by wind and tide, is always eroding exposed portions of the seaboard; and even such lesser influences as rain and frost assist in disintegrating cliffs composed of softer strata.

The main object of reclaiming land from the sea is to increase the area of ground available for cultivation. Land which has been raised by accretion nearly to high-water level can be shut off from the sea by works of a simple and inexpensive nature, and the fresh alluvial soil thus obtained is generally very fertile.

Accretion in estuaries takes place very slowly under ordinary conditions. Although at any one time the sheltered areas may be large and the deposit of silt fairly rapid, not much permanent accretion will take place owing to the frequent shifting of the channels. Directly, however, a fixed channel is secured by the embankments of training walls, accretion progresses rapidly and uninterruptedly by the deposit of sediment in the slack-water behind the embankments and at the sides of the estuary; and this is especially the case if the training works are raised to the level of high water, for this has the effect of restricting the greater part of the scour of tide and fresh-water discharge to the one fixed channel. The rate of accretion varies with the shelter of the site and the amount of sediment carried by the water; but by degrees the foreshores, in the upper portion and at the sides of the embanked estuary, are raised sufficiently for samphire to make its appearance, and, later on, a coarse grass. Ultimately the time arrives when the water may be altogether excluded by the construction of enclosing embankments; these must be raised above the level of the highest tide, and should have a flat slope on the exposed side, protected, in proportion to exposure and depth of water, against the face with clay, sods, fascines or stone pitching.

In the intermediate stages of the process outlined above much may be done to promote the growth of accretion, or warping as it is termed, and to ensure the fertility of the reclaimed land. The deposit of warp is accelerated by anything which tends to reduce the flow and consequent scour of the ebb-tide over the
foreshore: thus considerable advantage will accrue from placing rows of faggots or sods across the lines of flow; and banks, enclosing the higher portions of the foreshore, may often be constructed so as materially to increase the period of stagnation, near high tide, of the silt-bearing water upon the lower adjacent foreshore. The light, fertilizing alluvium only deposits in shallow water at high tide, and where there are no tidal currents. The final enclosure, therefore, should not be effected until this deposit has taken place. The enclosing works, also, should be so carried out that increasing shelter may favour the deposits of this alluvium during construction. A final and rapid deposit can sometimes be effected by making sluices in the banks: the turbid water is admitted near high tide, and retained until the whole of its silt has been deposited, the clear water being allowed to escape slowly towards low tide. Premature enclosure must be guarded against; it is more difficult, the coast greater, the reclaimed land is less fertile and, being lower, less easy to drain.

The practice of reclaiming land in British estuaries is a very ancient one. The Romans effected reifications in the Fen districts; the enclosing of Sunk Island in the Humber was begun in the 15th century, and now produces an annual revenue of something like £5,000; large reifications in the Dee estuary took place in the 18th century; and, in recent times, works have been carried out in the estuaries of the Seine, the Ribble and the Tees.

In the reclamation of land adjoining the sea-coast, sites where accretion is taking place are obviously the most suitable. Marsh lands adjoining the sea, and more or less subject to inundation at high tides, can be permanently reclaimed by embankments; but these, unless there is protection from sand dunes or a shingle beach, require to be stronger, higher, with a less steeply inclined and better protected slope than is required in estuaries. The width of the bank will generally prevent percolation of water at the base; but if there is any danger of infiltration, owing to unsuitability of material, a central core of puddled clay or a row of sheet-piling should be employed. Waves over-topping the bank will quickly cause a breach, and produce disastrous results; the height of the bank must, therefore, be calculated to meet the case of the severest on-shore gale coinciding with the highest spring tide. Undermining, caused by the action of waves on the beach, is liable to occur if exposed sites; this may be prevented by a line of sheet-piling along the outer toe of the bank.

Sea-coast embankments should not generally be constructed farther down the foreshore than half-tide level, as the cost of construction and maintenance would increase out of all proportion to the additional area obtained. It is, as a rule, more economical to reclaim a large area at one time, instead of enclosing it gradually in sections, as the cost varies with the length of embankment; it is, however, more difficult to effect the final closing of a bank, where a large area is thus reclaimed, on account of the greater volume of tidal-water flowing in and out of the contracted opening. The final closing of a reclamation embankment is best accomplished by leaving a fairly wide aperture, and by gradually raising a level bank across its entire length. The enclosed area may be left full of water to the height of the unfinished bank, or the tide-water may be allowed to escape and enter again by sluices in the finished sections. The embankments in Holland are closed by sinking long fascines matted together and strengthened with clay and stone, and effectively withstand the scour through the gap; the two terminal slopes of the finished sections are similarly protected.

There are many examples of sea-coast reclamation: Romney marsh was enclosed long ago by the Dymchurch wall (see fig. 1), and a large portion of Holland has been reclaimed from the sea by embankments (see fig. 2); the reclamation bank for the Hodbarrow iron mines (see fig. 3) illustrates the use of puddled clay to prevent infiltration.

The repair of a breach effected in a completed reclamation embankment is a more difficult task than that of closing the final gap during construction; this is owing to the channel or gully scoured out upon the opening of the breach. When a breach occurs which cannot be closed in a single tide, the formation of an over-deep gully may to some extent be prevented by enlarging the opening. Breaches in embankments have been closed by sinking barges across the gap, by piling and planking up, by lowering sliding panels between frames erected to receive them, and by making an inset wall or bank round the breach. By the last-mentioned method the new connecting bank can be formed on solid ground, and the necessary width of opening obtained to obviate excessive scour during the influx and efflux of the tide over the bank while it is being raised.

The gradual drying of reclaimed land lowers the surface some two or three feet; the land therefore becomes more liable to inundation after reclamation than before. Accordingly, it is most important to prevent breaching of the bank by promptly repairing any damage caused by storms; and if a breach should occur, it must be closed at the earliest possible opportunity.

The protection of the coast-line from encroachment by the sea is a matter of considerable importance and great difficulty: the more rapid the erosion, the more exposed must be the site, and, consequently, the more costly will be the construction and maintenance of protective works. These are of two kinds: sea-walls or banks, and groynes.

Upright sea-walls with some batter on the face have been constructed along the frontage of many sea-side towns, with the double purpose of making a promenade or drive, and of affording protection to the town. A very sloping and also a curved batter breaks the stroke of the wave by facilitating its rising up the face of the wall, but the force of the recoil is correspondingly augmented. A wall with a vertical face offers more direct opposition to a wave, minimizes the tendency to rise, and, consequently, the recoil; while a stepped face tends to break up both the ascending and recoiling wave in proportion to the recession of the steps, but there is a corresponding liability to displacement of the blocks composing the wall. The concrete sea-walls erected in front of Hove, Margate, and the north cliff at Scarborough (see figs. 4, 5, 6) exhibit straight, stepped, and curved forms of batter. The curvature of the last-named wall, though diverting the coil at its base, did not prevent erosion of the shale bed on which it was founded, and a protective apron in front of the toe had to be added subsequently.

The Beaconsfield sea-wall at Bridlington (see fig. 7) is stepped and slightly curved; it has a stone face with concrete backing,
RECLAMATION OF LAND

strengthened at intervals by counterforts. The thickness of the wall varies from 11 ft. 6 in. at the base to 3 ft. at the top, and is surrounded by a dressed cornice and coping; the length is 340 yards. The work was constructed, in 1898, at a cost of £10,000, or £29. 8s. per lineal yard.

Walls with almost vertical faces, or slightly stepped, appear to be the best. Unless, however, the foreshore consists of hard rock, or a raised beach maintained by groynes, a wall of this kind should be protected by an apron, in order to prevent the destructive undermining to which such forms of wall are necessarily liable.

Where the coast is fringed with sand dunes, and the beach protected from erosion by a regular series of groynes, as at Ostend (Belgium), the sand dunes, or an embankment for a promenade in front of them, may be sufficiently protected by a simple slope, paved with brickwork or masonry, and having a maximum inclination of two to one. The paving requires to be laid on a bed of clay, rubble or concrete. Parts of the sea bank at Ostend had to be protected from undermining at the toe with piles and planks, and an apron of concrete or pitching, laid on fascines, extending down the foreshore. For the parts above high-water mark a short paved slope, with moderate protection at the toe, has been found sufficient. The top face of these slopes is reflexed so as to protect the esplanade from surf during storms.

Sea-walls are very costly and, while temporarily resisting, do not diminish, but actually increase, the erosive action of the sea. In short, sea-walls are a most unsatisfactory type of protective work.

The protection afforded to the coast by groynes is based on a totally different principle, which may be summarized as that of promoting natural accretion by the construction of artificial shelter. Along most coasts there is a littoral drift of sand or shingle; by means of groynes, projecting from the coast-line down the beach, this drift may be intercepted so as to produce accretion to the foreshore, where previously there has been constant erosion. The problem, however, of coast protection by this method presents difficulties. Littoral drift is the product of erosion, and the fate of a large portion of this drift is to be deposited in deep water. Any scheme, therefore, of stopping erosion altogether by means of groynes would be purely chimerical; in the same way, partial failure of groynes, from lack of drift and inability to stop wastage, must be expected in many localities. Another difficulty may be illustrated by the action of such natural projections as Dungeness: this point, by completely arresting the easterly drift of shingle, causes a rapid accretion to the beach on the one side, but a corresponding denudation on the other. The old type of high groyne, erected at Cromer and Hastings, has produced the same undesirable result; moreover, the general effect of groyning certain portions of the foreshore is to render the adjacent unprotected portions more liable to erosion. Nevertheless, the benefit which may be derived locally from suitable groyning is very great. The timber groynes erected between Lancin and Shoreham raised the shingle beach sufficiently to cause high-water mark to recede 85 ft. seawards in the course of a few years.

The eroding action of the river Scheldt in front of Blankenberghe has been arrested by carrying out groynes at right angles to the coast-line, and down to below low water (see figs. 9, 10). These, on the average, are about 820 ft. long and 680 ft. apart; they are made wide, with a curved top, raised only slightly above the beach, so as to minimize the scour from currents and wave action, and facilitate the ever
distribution of drift over the protected area. They are constructed with a foundation of fascines and concrete, faced with brickwork or stone pitching. The result has been the formation of a gently sloping beach which reduces wave action; such loss, too, as is still occasioned by storms is speedily made good by natural accretion in moderate weather. The Blankenbergh groynes are too expensive a type for ordinary use.

The beach at Bridlington, which rests on boulder clay, was rapidly disappearing owing to the increased scour due to the sea-walls. Accordingly, groynes (see figs. 11, 12) made of 14 ft. × 9 in. × 9 in. pitch-pine piles, and 11 in. × 4 in. planking, were erected along the foreshore. The piles originally projected about 6 ft.; but, to prevent heaping up of sand to windward with denudation to leeward, the planking was never raised more than two strokes above sand-level; fresh planks were added as the sand rose. The south-easterly gales are said to be the most erosive here, and prevalent during the winter months; on this account the groyne was given an inclination of 10° south of east, that is 10° from the perpendicular. It may be doubted whether this was the best angle, but the result has been very satisfactory. The cost of construction was from 12s. 3d. to 18s. per lineal foot.

The sand-banks at the entrance to Poole Harbour have been protected by groynes (see fig. 13) inclined at slightly varying angles, some yielding better results than others. This is a good example of the important work which may be accomplished by groyning. Unprotected, a breach would soon have been effected in these sand-banks; with a double entrance to the bay the present deep channel would have silted up, and Poole Harbour would have been practically destroyed.

It is evident that the efficacy of groynes in collecting drift is proportionate to the distance which they can be carried out seawards, and that they should always be extended to low-water mark; whilst, by raising them only slightly above the beach, the accumulation of drift to leeward is promoted, the passage of drift over the obstruction being facilitated and the scour of the waves diminished. By this means, and by gradually raising and extending the groynes as the drift accumulates, the general elevation of the beach can be secured. Drift generally travels in both directions along a coast, veering with the wind; thus the prevailing wind determines the preponderating travel of the drift. Groynes are usually constructed at right angles to the shore, but it is believed that increased benefit may be obtained by inclining them slightly. Some engineers have advocated the extension of groynes below low-water mark; and as wood when permanently submerged is specially liable, even when creosoted, to be attacked by the teredo and limnoria, the use of reinforced or ferro-concrete has been suggested as the most suitable material for submarine groyning. These suggestions, however, and many other current theories on groyning, require to be demonstrated by repeated experiments.

For a useful bibliography of the subject see British Parliamentary Reports, Coast Erosion and the Reclamation of Tidal Lands, Cd. 3684, Appendix No. X. pp. 146–158.

RECLUS, JEAN JACQUES ELISÉE (1830–1905), French geographer, was born at Sainte-Foy la Grande (Gironde), on the 15th of March 1830. He was the second son of a Protestant pastor, who had a family of twelve children, several of whom acquired some celebrity either as men of letters, politicians or members of the learned professions. His education, begun in Rhenish Prussia, was continued in the Protestant college of Montauban, and completed at the university of Berlin, where he followed a long course of geography under Karl Ritter. Withdrawing from France in consequence of the events of December 1851, he spent the next six years (1852–57) visiting the British Isles, the United States, Central America, and Colombia. On his return to Paris he contributed to the Revue des deux mondes, the Tour du monde and other periodicals a large number of articles embodying the results of his geographical work. Among other works at this period was an excellent short book, Histoire d'un ruisseau, in which he traces the development of a great river from source to mouth. In 1867–68 he published La Terre; description des phénomènes de la vie du globe, in two volumes. During the siege of Paris, Reclus shared in the aerostatic operations conducted by M. Nadar, and also served in the National Guard, while as a member of the Association Nationale des Travaillleurs he published in the Cri du Peuple a hostile manifesto against the government of Versailles in connexion with the Communist rising of the 18th of March 1871. Continuing to serve in the National Guard, now in open revolt, he was taken prisoner on the 5th of April, and on the 16th of November sentenced to transportation for life; but, largely at the instance of influential deputations from England, the sentence was commuted in January 1872 to perpetual banishment. Thereupon, after a short visit to Italy, he settled at Clarens, in Switzerland, where he resumed his literary labours and, and, after producing the Histoire d'une montagne (a companion to Histoire d'un ruisseau), wrote nearly the whole of his great work, La Nouvelle Geographie universelle, la terre et les hommes, 19 vols. (1875–94). This is a stupendous composition, profusely illustrated with maps, plans, and engravings, and was crowned with the gold medal of the Paris Geographical Society in 1892. An English edition appeared simultaneously, also in 19 vols., the first four by E. G. Ravenstein, the rest by A. H. Keane. Extreme accuracy and brilliant exposition form the leading characteristics of all Reclus's writings, which thus possess entire literary and scientific value. In 1882 Reclus initiated the "Anti-Marriage Movement," in accordance with which he allowed his two daughters to marry without any civil or religious sanction whatever. This step caused no little embarrassment to many of his well-wishers, and was followed by government prosecutions, instituted in the High Court of Lyons, against the anarchists, members of the International Association, of which Reclus and Prince Kropotkin were designated as the two chief organizers. The prince was arrested and condemned to five years’ imprisonment, but Reclus, being resident in Switzerland, escaped. After 1892 he filled the chair of comparative geography in the university of Brussels, and contributed several important memoirs to French, German and English scientific journals. Among these may be mentioned "The Progress of Mankind" (Contemp. Rev., 1896); "Attilla de Gerando" (Rev. Geograph., 1898); "A Great Globe" (Geog. Journ., 1898); "L'Extrême-Orient" (Bul. Antwerp Geo. Soc.,
RECOGNIZANCE—RECORD

1868), a thoughtful study of the political geography of the Far East and its possible changes; "La Perse" (Bul. Soc. Neuchâteloise, 1899); "La Phénicie et les Phéniciens" (ibid., 1900); La Chine et la diplomatie européenne ("L'Humanité nouvelle" series, 1900); L'Enseignement de la géographie (Inst. Géograph. de Bruxelles, No. 5, 1901). Shortly before his death Reclus had completed L'Homme et la terre, in which he set the crown on his previous greater works by considering man in his development relative to geographical environment. Reclus died at Thurout, near Bruges, on the 4th of July 1905.

RECOGNIZANCE (from Lat. recognoscere, to acknowledge), a term of English law usually employed to describe an obligation of record, entered into before some court or magistrate duly authorized, whereby the party bound acknowledges (recognizes) that he owes a personal debt to the Crown, with a defasance, i.e. subject to a condition that the obligation to pay shall be avoided if he shall do some particular act—as if he shall appear at the assizes, keep the peace, or the like. The system of taking recognizances in favour of the Crown at an early date superseded the common law practice as to pledges and main-prize (see re Nottingham Corporation, 1807, 2 Q.B. 502, 514).

Blackstone's definition extends the term recognizance to bonds in favour of private persons. But at present it is rarely if ever used in this sense. Recognizances are now used almost solely with reference to criminal proceedings. In the Court of Chancery it was the practice to require recognizances from the guardian of a ward of court that the ward should not marry or leave the country with the privy of the guardian and without the leave of the court. The security given by a receiver appointed by the High Court is still in the form of a recognizance acknowledging a debt to named officers of the court, and securing it on the real and personal estate of the receiver. The act 33 Geo. III. c. 2, extended to Ireland by Pouying's Act, and by the terms of the commission of the peace, justices of the peace have jurisdiction to cause to come before them or any one of them "all those who to any one or more of our people concerning their bodies or the firing of their houses have used threats to find sufficient security for the peace or their good behaviour towards us and our people; and if they shall refuse to find such security, then there in their prisons until they shall find such security to cause to be safely kept." The security taken is by recognizance of the party and his sureties, which can be forfeited on conviction of any offence which is a breach of the conditions of the recognizance.

The procedure under the act of 1360 and the commission is usually described as exhibiting articles of the peace or swearing the peace. The High Court (King's Bench Division) has the same power as justices in quarter sessions. This procedure is in practice supplanting the process of record (from record in the French, as a roll or book) in England, so far as concerns courts of summary jurisdiction, by an equivalent but more modern procedure (42 & 43 Vict. c. 49, s. 25). Recognizances ordered under these enactments cannot be forfeited or as it is termed "posthumously void" if a court made upon proof of breach of the conditions, or of a conviction involving such breach. The procedure for estreats is governed by the Levy of Fines Acts 1822 and 1833, and by 16 & 17 Vict. c. 32.

There is also a general jurisdiction on conviction of misdemeanour to put the offender under recognizances to keep the peace and (or) be of good behaviour in addition to or in substitution for other punishment. This power is specifically applied by the Criminal Law Consolidation Act of 1861 to all offenders convicted under any other enactment or any other enactment or any other enactment or any other enactment or any other enactment and all other recognizances, except those relating to debt, are ordered upon the facts and circumstances of the case, and not upon the general policy of the individual. Recognizances are, however, most used with reference to proceedings before conviction and judgment. In preliminary inquiries into indictable offences the inquiring justices take recognizances to ensure the attendance of the witnesses if they are required if an accused is to stand and prosecute or give evidence. As to witnesses this power was first given in 1554 (1 Ph. & M. c. 13). The procedure is regulated by the Indictable Offences Act 1848 (11 & 12 Vict. c. 42) as amended in 1867 (30 & 31 Vict. c. 35) and the forms of recognizance are scheduled to the act of 1848. In the case of inquiries of murder or manslaughter taken before a coroner a recognizance (or covenant) is required (42 & 43 Vict. c. 71, s. 5). The recognizances taken are returnable under penalty to the court of trial, which orders their estray in the event of breach of the conditions.

The powers as to the recognizances of persons prosecuted summarily are given by the Summary Jurisdiction Acts 1848 and 1879; and in the event of appeals to quarter sessions or by special case to the High Court from courts of summary jurisdiction, recognizances may be required (42 & 43 Vict. c. 49, ss. 31, 33). On the transfer of indictments from inferior to superior courts recognizances to pay the costs on conviction are also required (Crown Office Rules, 1906). In certain cases the police have power to require recognizances on their entering into a recognizance; and governors of prisons are allowed to release prisoners on bail on compliance with the terms on which it is allowed by the committing justices.

By the is called Cha. rec. in Asiam cap. for. 5 c. 71, s. 2 (1) a recognizance, whether obtained or entered into on behalf of the Crown or otherwise, does not operate as a charge on land or or any interest on land or on the unpaid purchase money for any land, unless a writ or order for the purpose of enforcing it is registered under s. 5 of the Land Charges, &c., Act 1888 (51 & 52 Vict. c. 51) in the office of the Land Registry. This enactment is clearly applicable to receivers' recognizances, supra; and on the use of paid land security for registration of documents and an official certificate can be obtained affirming or negating the existence of a registered entry (Conveyancing Act 1882, s. 2). By s. 30 of the Bankruptcy Act 1883, a discharge in bankruptcy discharges the debtor from all debts and liabilities with which he is concerned at any time of the bankruptcy unless the Treasury certifies in writing its consent to the discharge.

In Scotland the place of recognizances is filled by cautions; a caution in "law-burrows" corresponds very nearly to a recognizance to keep the peace.

By the United States recognizances are used for much the same purposes as in England. (W. F. C.)

RECONNAISSANCE (from Fr. reconnaître, to recognize, Lat. recognoscere), a military term denoting the reconnoitring or examination of an enemy's position or movements, or of a tract of ground. Reconnaissances naturally vary indefinitely according to the purposes for which they are undertaken. A topographical reconnaissance is practically a survey of a tract of country or route, comprising both a map and a report as to its advantages and disadvantages. All reconnoitring work of this character is done by officers with small patrols, escorts or assistants. Stratagetical reconnaissance is performed by contact squadrions, which send forward officers and patrols to find the enemy. Tactical reconnaissance falls to the lot of troops of all arms, whether in contact with the enemy or for self-protection. A reconnaissance by a large force of all arms with the idea of provoking an enemy into showing his hand, if necessary by calling for a battle, is called Cha. rec. in Asiam cap. for. 5 c. 71, s. 2.

RECORD (Lat. recordari, to recall to mind, from cor, heart or mind), a verb or noun used in various senses, all derived from the original one of preserving something permanently in memory. In this article, however, we are only concerned with documentary records, or archives. In its accurate sense a record is a book regularly drawn up for a legal or administrative purpose and preserved in proper custody to perpetuate the memory of the transaction described in it; for the most part it forms a link in a complicated process, and unless the connexion between it and the other documents making up the process has been preserved, a portion of its meaning will have perished. The first care, therefore, of the custodian of records should be to preserve this connexion, where it exists. In the majority of countries a prevision has been made for the record; there is a custodian who has his duty to collect and arrange his documents. There are few countries in which records have not passed through a period of neglect; each office of state has kept or rather neglected its own papers; each court of justice has been the keeper of its own records; the student has been paralysed by a multitude of repositories among which he vainly sought the documents he required. To this stage two systems have succeeded; the system of centralization both of records and of
staff; and the system under which the records are local repositories and the staff is centralized. There are of course countries which cannot be brought under either of these formulas. But for the most part it will be found that the second system has prevailed; there are a central office for records of state, provincial offices for legal records and those of local administration, town offices for municipal records, and a staff of archivists depending more or less strictly upon the central office. In England the first system has been preferred; almost all the records that can be collected have been gathered into the central office. In the future, indeed, it is inevitable that collections of administrative records should grow up for each county; but there is at present no means of ensuring their arrangement and preservation. Many towns possess old and valuable collections of municipal archives, and over these also the central office has no control. It would be absurd to affirm that such control is needed for the preservation of the documents; but it is a curious fact that the English government, which has the most important records more freely than any other, should have refrained from establishing any system of administration for records in general.

The following article is intended to give a full account of the administration and nature of the records of Great Britain, and brief notices of those of other countries concerning which information is obtainable. It may be noticed that the directory of the learned world published by Trübner at Strassburg under the title Minerva will be found a useful guide to the situation and staff of repositories of records.

**England.**

The most important repository of English records is the Public Record Office, Chancery Lane, London, established under the Act 1 & 2 Vict., c. 94. The head of the office is the Keeper for the being, and the staff consists of the deputy-keeper, secretary, assistant-keepers and clerks, with a subordinate staff.

Until the establishment of this office, the records of the various courts of law and government offices were stored in separate places, mostly of an unsuitable nature, whose contents were inaccessible and unknown. The Tower of London contained the records of the Chancery, which were kept in fair order; the records of the Rolls for the time being; and the staff consists of the deputy-keeper, secretary, assistant-keepers and clerks, with a subordinate staff.

The result of this committee was the appointment of a royal commission charged with the arrangement and publication of the public records and the control of all public repositories. This commission was renewed from year to year and did not expire until 1800. The work of the commission was generally exercised; it was chiefly by means of committees of the House of Lords, to procure reforms in the custody of documents whose value was well understood. In the reign of Queen Anne, an act was passed by Parliament, and the necessary preliminary measures were taken.

This act was an important step in the direction of making such documents as could be found bearing upon foreign politics; and this drew fresh attention to the question of custody. In 1731 the disastrous fire in the Cottonian Library produced a committee of the House of Commons and another report. But it was not until 1800 that any serious steps were taken. In that year a committee of the House of Commons presented a valuable report dealing with all the public records in repositories in England and Scotland. The result of this committee was the appointment of a royal commission charged with the arrangement and publication of the public records and the control of all public repositories. This commission was renewed from year to year and did not expire until 1800. The work of the commission was generally exercised; it was chiefly by means of committees of the House of Lords, to procure reforms in the custody of documents whose value was well understood. In the reign of Queen Anne, an act was passed by Parliament, and the necessary preliminary measures were taken.

The work of the commission was generally exercised; it was chiefly by means of committees of the House of Lords, to procure reforms in the custody of documents whose value was well understood. In the reign of Queen Anne, an act was passed by Parliament, and the necessary preliminary measures were taken.

**Exchequer Records.**—The records of the administrative divisions of the Exchequer (ga.1) are here described under its several divisions.

**Upper Exchequer, or Exchequer of Audit.**—(a) Lord Treasurer's Remembrancer's Office, or office of final audit. The result of the final audit, which was noted in the Pipe and Chancellor's Rolls. These consist of a roll for 3 Henry I. and a duplicate series extending from 2 Henry II. to 2 William IV. The Record Commission has printed the following rolls: Pipe Rolls, 31 Henry I.; 1 Richard I.; Chancellor's Rolls, 5-24 Henry II.

**Accounts.**—These contain the records of the preliminary audit of accounts other than county accounts; they are more compactly grouped than those of the Exchequer of Audit, which are closely connected with them are the Enrolled Accounts, which deal with the more important accounts separately. It should be noted that the final audit is not recorded upon either Foreign Rolls or Enrolled Accounts, but must be sought on the Pipe Roll, unless the account is found to be quit or to have a balance due to him. The Record Office has published a classified list (No. XL.) of the Foreign and Enrolled Accounts taken from all the foregoing rolls of rolls of the Exchequer of Audit, but does not publish such lists for the later times. The Enrolled Accounts.—A list (No. II.) of these records with an introduction has been published by the Record Office. The series begins in the 16th century, and from the 17th century is fairly complete.

**Originalia Rolls** (2 Henry III. to 1837), or extracts from the Chancery Rolls communicated to the Exchequer for its information and guidance. Latin abstracts of the rolls from Henry III. to Edward III. are entered in the Record Commission as Abbreviatio Rotularum Originalium (2 vols. idio).

**Lord Treasurer's Remembrancer's Memoranda Rolls.**—These contain the letters received and issued by the Exchequer and not the accounts for the same. They have been published from 1 Henry III. to 1848. Edward Jones's Index to the records contains a few scattered references to them; and many extracts will be found in the notes to Thomas Maddox's History of the Exchequer.

**Judaica.**—The only judicial proceedings on the Lord Treasurer's Remembrancer's side are in cases connected directly with the revenue. These are enrolled upon the Memoranda Rolls; and for the period 35 Edward III. to warrants, see the Books, King's Remembrancer's Memoranda Rolls (1 Henry III. to 13 Victoria). These run parallel with those of the Lord Treasurer and to a large extent contain the same matter. Adam Martin's Index to Exchequer Records contains a certain number of references to them.

For the reign of Edward VI., returns were made into the Exchequer by commissioners appointed to take inventories of Church Goods. Volumes of these for several counties are being published by the Alcuin Club (see Mély et Bishop, Bibliographie générale des inventaires, vol. iv.).

**Judicial.**—The court of Exchequer on the King's Remembrancer's side was a court of equity held before the lord treasurer, the chancellor of the Exchequer and the barons. The usual records of a court of equity, Bills and Answers, Decrees and Orders, Affidavits and other subsidiary documents exist for it. Martin's Index to Exchequer Records contains references to the Decrees and Orders.
Of the proceedings under special commissions issuing from this court a descriptive catalogue (Elizabet to Victoria) has been published in the 38th Report. Depositions taken by commission (Elizabet to George III.) are catalogued in the Reports 38–42. A catalogue of the principal rolls is contained in the Receipt and Issue Rolls showing the payments made to and by the Exchequer. Many of these were used subsequently in the depositions and records from Henry III. to George III. The last book (Rolls of 17 Henry IV. to 27 Charles I.) contains the records of judicial writs issued under the great seal with a note of the fine or fee paid; also of letters of appointment to offices and letters relating to the government of the colonies. The Record Commission has also published two volumes containing the records of the registers of the King under the title Rotuli de Oblatis et Finibus; for the reign of Henry III. they only published two volumes of Excerpta et Rotuli Finium Regis Henrici III; and these are also well worth consulting. The catalogue of the entries on these rolls down to the reign of Edward IV. was published by Thomas Carte in two volumes. Of the French Rolls (16 Edw. III. to 26 Charles I.) the records have been carefully printed in the 44th Report; and those for the reign of Henry VI. in the 48th Report. The Gastron Rolls (38 Henry III. to 7 Edw. IV.) the earlier rolls have been published in full in the Documents Selecta published by the French government under the care of M. Le Franc-Marchant and Bérel of the French College. Norman Rolls (1 John to 1 Henry V.) those for the reign of John and that for 5 Henry V. have been printed in full in one volume by the Record Commission; to the remainder a calendar will be added. The 44th Report also contains those for the reign of Edward II. who was one of the successful candidates for the office of King. The books here mentioned deal with some rolls now placed in other classes.

Other rolls contain letters under the great seal relating to Ireland, Scotland and Wales. Of these the Record Commission printed the first volume (19 Edw. III. to 26 Charles I.) and this contains numerous letters of protection contained in them. For the Welsh and Irish Rolls there is only a single calendar in Ayloffe's Calendar of Ancient Charters. The Roman and Alman Rolls have been printed in the Indexes and Records of the Exchequer, and the Liberate Rolls will be found there. The Liberate Rolls (2 John to 14 Henry VI.) contain the enrolments of writs for the issue of money out of the Exchequer. The rolls of 2–4 John have been printed in full by the Record Commission.

Venerable Bishops forming Part of the Process of Issuing Letters under the Great Seal.—These are known as Chancery warrants, and consist of Privy Seals, Signed rolls and other documents forming parts of warrants. Series I. of these documents extends to the end of the reign of Richard III., and Series II. to the end of the reign of Henry VII., containing Series IV. with that of William IV., while Series V. is still in progress. Series I. and II. are arranged in chronological order (Series I. being also classified); the remainder are in monthly bundles. The warrants for the reign of Henry VIII. are calendared in the Records of the Chancery. The records for the period 28 Henry III. to 2 Richard III. are calendared in the 3rd Report. These may be placed the Inquisitions ad quod damnum. Of these the Record Office has published four volumes of Inquisitions Post Mortem, Nos. XVII. and XXIII. for the period 28 Henry III. to 2 Richard III.

Documents drawn up for the Information of the Chancery.—The most important of these are the inquiries held under writs issued from the chancery. The first series of these (Henry III. to Richard II.) is entitled Inquisitions Post Mortem including analogous documents relating to the feudal tenure of land, Criminal Inquisitions and Miscellaneous Inquisitions. The Record Office has published three volumes of Inquisitions Post Mortem; in 1502 and 1504 and 1506. The calendars refer to the old arrangements of these inquiries into two series, known as Inquisitions Post Mortem and Inquisitions Post Mortem &c. A distinction of title which concealed the identity of the documents so described has been made. The calendars contain many inaccuracies and omit much useful information. To supply some of these defects for the period Henry III. to Edward I. the Record Office published the Calendarium Genealogicum, but this work does not attempt to deal with the lands mentioned in the Inquisitions. The Chancery calendars form the basis of the classes of inquisitions are all placed together. One volume of a calendar to the Inquisitions Post Mortem for the reign of Henry VII. has appeared. Certificates of Gilds are returns made under the statute of 3 Richard II. and those English have been printed by I. and L. Toulmin Smith for the Early English Text Society. Charitable Uses: a list (No. X.) of all inquisitions and decrees of commissioners.
appointed under two statutes of Elizabeth to examine and rectify abuses of charitable bequests has been published by the Record Office. *Forests (Chancery)* contain perambulations and proceedings before justices in eyre of the forest. The perambulations for counties of England and Wales have been edited by G. J. Turner in *Select Pleas of the Forest* (Selden Society).

*Scottish Documents.*—Five rolls relating to the policy of Edward I. towards Scotland. The first two contain the proceedings touching the death of John, Duke of Scotland, and are printed for the Scottish Record Commission, 1880. The other three are described in J. Bain's *Calendar of Documents relating to Scotland.*

Most of these together with the earlier Forest proceedings are included in the *Miscellanea of the Chancery*, which contains numerous other documents and statistics of many of those relating to foreign affairs in the *Foederas.*

(2) Chancery Judicial.—These may be divided into *Proceedings, or Bills and Answers, &c.* filed by the parties; *Decrees and Orders of the court,* and *Affidavits* and other documents connected with the *Court of Chancery,* as *Proceedings* (Richard II. to Philip and Mary), comprising documents of all three classes, is arranged roughly in chronological order. The Record Office has published three volumes of a descriptive list (No. XXI., vol. I. to vol. III.) containing the titles of the proceedings, which are classified, and the two bundles have been printed in full in the Record Commission's *Calendar of Proceedings in Chancery, Elizabeth.* Other specimens are printed in *Select Pleas of the Chancery* (Selden Society), edited by the B. F. Maitland, and the *Ancient* and *Modern* Chancery, shafted alphabetically under the names, the proceedings before justices in the reigns of Edward I. and Edward VIII. The Bills and Answers of the reign of Charles II. Messrs Phillimore and Fry have published in the *Index Library of the British Record Society* an index taken from Topham's manuscript index in the Record Office. The Society has also published, on a strong continuous index* to the records of the Court of Chancery of the 17th century.*

The publication of the proceedings of the Court of Chancery in England has been edited by F. W. Selden, and the *Record Office* has published *the Court of Chancery, 1509-1707,* and *the Court of Chancery, 1707-1830,* and *the Court of Chancery, 1830-1858.*

(3) Chancery Calendar.—The proceedings of the Court of Chancery have been published in a series of volumes under the title of *Proceedings* (No. XXX.); and specimens have been printed in *Select Pleas of the Chancery* (Selden Society), by the B. F. Maitland, and the *Ancient* and *Modern* Chancery, shafted alphabetically under the names, the proceedings before justices in the reigns of Edward I. and Edward VIII. The Bills and Answers of the reign of Charles II. Messrs Phillimore and Fry have published in the *Index Library of the British Record Society* an index taken from Topham's manuscript index in the Record Office. The Society has also published, on a strong continuous index* to the records of the Court of Chancery of the 17th century.*

The publication of the proceedings of the Court of Chancery in England has been edited by F. W. Selden, and the *Record Office* has published *the Court of Chancery, 1509-1707,* and *the Court of Chancery, 1707-1830,* and *the Court of Chancery, 1830-1858.*

(4) Chancery Calendar.—The proceedings of the Court of Chancery have been published in a series of volumes under the title of *Proceedings* (No. XXX.); and specimens have been printed in *Select Pleas of the Chancery* (Selden Society), by the B. F. Maitland, and the *Ancient* and *Modern* Chancery, shafted alphabetically under the names, the proceedings before justices in the reigns of Edward I. and Edward VIII. The Bills and Answers of the reign of Charles II. Messrs Phillimore and Fry have published in the *Index Library of the British Record Society* an index taken from Topham's manuscript index in the Record Office. The Society has also published, on a strong continuous index* to the records of the Court of Chancery of the 17th century.*

The publication of the proceedings of the Court of Chancery in England has been edited by F. W. Selden, and the *Record Office* has published *the Court of Chancery, 1509-1707,* and *the Court of Chancery, 1707-1830,* and *the Court of Chancery, 1830-1858.*

(5) Chancery Calendar.—The proceedings of the Court of Chancery have been published in a series of volumes under the title of *Proceedings* (No. XXX.); and specimens have been printed in *Select Pleas of the Chancery* (Selden Society), by the B. F. Maitland, and the *Ancient* and *Modern* Chancery, shafted alphabetically under the names, the proceedings before justices in the reigns of Edward I. and Edward VIII. The Bills and Answers of the reign of Charles II. Messrs Phillimore and Fry have published in the *Index Library of the British Record Society* an index taken from Topham's manuscript index in the Record Office. The Society has also published, on a strong continuous index* to the records of the Court of Chancery of the 17th century.*

The publication of the proceedings of the Court of Chancery in England has been edited by F. W. Selden, and the *Record Office* has published *the Court of Chancery, 1509-1707,* and *the Court of Chancery, 1707-1830,* and *the Court of Chancery, 1830-1858.*
in character from the State Papers Domestic. The Domestic Papers relating exclusively to Ireland have been calendared under the title of State Papers, Ireland, for the years 1599–1601 and 1603–1605, with a special volume dealing with the papers concerning Admistrative and Judicial business. From 1670 these papers are calendared in the Domestic volumes.

Scotland.—Originally there were in the State Paper Office two series of papers relating to Scotland, State Papers Domestic, Border Papers, and State Papers Foreign, the first containing mainly the records of the Court of Session and the Warden's of the Marches; and State Papers Foreign, Scotland, before the union of the two crowns. The first calendar of these was a Calendar of State Papers, Scotland, 1509–1603, containing brief notes, published in 1891, which give details of the Border Papers which were removed from their places without any record of the removal. Next came the Calendar of State Papers Foreign, in which were included apparently all the Border Papers for the Scottish Colonies, but which included only the later notes; however, were made of the papers so taken. Out of the original 75 volumes of Border Papers only 36 remained. At a later date the papers drawn for the Foreign Calendar were restored and now the first 15 volumes of the series, while the 36th volume originally remaining have now become the final 23. The same time the State Papers Foreign, Scotland, were annexed, and became State Papers Domestic, Scotland. In their present arrangement the Border Papers have been calendared in the following volumes: Vols. 1–19 in the Scottish Register Office Calendar of Border Papers, 1500–1601. The State Papers Domestic, Scotland, from 1547 onwards, are being fully calendared in the Scottish General Register Office Calendar of Border Papers, 1540–1601. The Border Papers from 1500 to 1547 are dealt with in the Letters and Papers of Henry VIII. (see below, Special Collections). A list of these three Classes has been published (No. III.).

State Papers Spanish.—These papers were calendared for the period 1547–1580. A few of these papers are also calendared in the first volume of the State Papers Spanish (see below under Spain). The Record Office has published a list of these (No. II.).

ColoniaL.—These papers are calendared in two sets an "East Indies" (1513–1634), which has been continued to 1639 by the India Office in Miss E. B. Sainsbury's Court Minutes of the East India Company (1574–1691).

In progress.

Departmental Records.—From time to time all the government departments, with the exception of the India Office, deposit some of their papers to the Record Office. The present series of Departmental Records, thus the Treasury, Home Office, Foreign Office, Colonial Office, Admiralty, War Office, Local Government Board, and Board of Trade have all placed important papers in the care of the Master of the Rolls. A calendar of the earlier Treasury Papers, which extends from 1660 to 1668 and 1720 to 1745 has been published; also a list of the Admiralty Records (No. XVII.). For each department a limiting date is fixed from time to time; documents before that time are used by students; later ones are only accessible under special conditions.

Subordinate and Independent Jurisdictions.—Palatinate of Durham.—For the earlier records see G. T. Lapsley's County Palatinate of Durham (Harvard Historical Series, vol. viii.), pp. 327–337. The Palatinate of Durham is the birthplace of Pepys. The Palatine Records are calendared in the 44th Report: and a volume (No. 2) contains transcripts of similar documents, calendared in the 45th Report. The records of the Office of the Bishop of Beverley, the Cursitor's Records also included in the Palatine Records, are treated as the private records of the Ecclesiastical Commission, and are only accessible under a special permit. To the judicial records the only printed means of reference is the list of John Haskins (Rolls, 37–40 to 78–Victoria) in the Record Office list of Pleas Rolls (No. IV.).

Palatinate of Chester.—The letters sent out from the chancery are enrolled upon the Chester Recorization Rolls (1 Edward II, to 34 Charles II, with a few rolls down to 1 William IV.) calendared in Record Office, 4th Report. They are calendared in the 4th Report. The Cursitor's Records of Chester are calendared among the Ministers' Accounts (List No. V.) of the county of Chester. The Inquisitions Post Mortem are calendared in Record Office, 4th Report. The Inquisitions Post Mortem and ad quod damnum (Edward III, to Charles I.) are indexed in the 25th Report. The cases are calendared, and the records are deposited at the Exchequer. The court of equity. Its records are Rolls and Answer (Henry VIII., to George IV.), calendared in the 25th Report up to Philip and Mary; and Decrees and Orders. The court of the justices of Chester was at common law; its Plea Rolls (4 Henry III, to 1 William IV.) were calendared in the 4th Report. But the records of the Court of Chancery, a court of equity. Its records are Rolls and Answer (Henry VIII., to George IV.), calendared in the 25th Report up to Philip and Mary; and Decrees and Orders. The court of the justices of Chester was at common law; its Plea Rolls (4 Henry III, to 1 William IV.) were calendared in the 4th Report. But the records of the Court of Chancery, a court of equity. Its records are Rolls and Answer (Henry VIII., to George IV.), calendared in the 25th Report up to Philip and Mary; and Decrees and Orders. The court of the justices of Chester was at common law; its Plea Rolls (4 Henry III, to 1 William IV.) were calendared in the 4th Report. But the records of the Court of Chancery, a court of equity. Its records are Rolls and Answer (Henry VIII., to George IV.), calendared in the 25th Report up to Philip and Mary; and Decrees and Orders. The court of the justices of Chester was at common law; its Plea Rolls (4 Henry III, to 1 William IV.) were calendared in the 4th Report. But the records of the Court of Chancery, a court of equity. Its records are Rolls and Answer (Henry VIII., to George IV.), calendared in the 25th Report up to Philip and Mary; and Decrees and Orders. The court of the justices of Chester was at common law; its Plea Rolls (4 Henry III, to 1 William IV.) were calendared in the 4th Report. But the records of the Court of Chancery, a court of equity. Its records are Rolls and Answer (Henry VIII., to George IV.), calendared in the 25th Report up to Philip and Mary; and Decrees and Orders. The court of the justices of Chester was at common law; its Plea Rolls (4 Henry III, to 1 William IV.) were calendared in the 4th Report. But the records of the Court of Chancery, a court of equity. Its records are Rolls and Answer (Henry VIII., to George IV.), calendared in the 25th Report up to Philip and Mary; and Decrees and Orders. The court of the justices of Chester was at com}
is obscure; an account of it is in the Record Office Index to the class (No. 1); but see also the Introduction to F. W. Maitland's Memoranda de Parlamento (Rolls Series, vol. 98), in which volume a number of these petitions are printed in full.

Diplomatic Documents.—In the Chapter House at Westminster was a collection of treaties and other documents connected with foreign affairs, and to these have been added other similar documents found there. Of these there is a descriptive list in the 45th and 46th Reports. A separate collection of so-called Diplomatic Documents from the chancery forms part of the Chancery Miscellanea.

Letters and Papers, Foreign and Domestic, of the Reign of Henry VIII.—This great collection of materials for the reign of Henry VIII. (Calendar of 20 volumes in 30) at present extends to the year 1547, and is intended to contain abstracts of all documents bearing upon that reign in the Record Office, the British Museum and other collections. Records of the Office and documents dealt with in this Calendar have sometimes been left in their original place of custody and sometimes transferred to a series of bound volumes known as Letters and Papers, Henry VIII. References will be found in the Calendar to a previous series of State Papers of the Reign of Henry VIII., printed by a Royal Commission for printing State Papers.

Miscellaneous Books.—The many books and registers preserved in the Record Office will be found described in the Handbook. The following have been printed:

Exchequer King's Remembrancer
Vol. 3. Book of Aids. (See Feudal Aids, published by Record Office.)
Vol. 4. Book of Knight's Fees. (See Feudal Aids.)
Vol. 5 & 6. Testa de Neville; printed by the Record Commission.

Vol. 17. A 16th-century transcript of an abstract of Kirkby's Quest for certain counties; used in Feudal Aids.
Vol. 28. Chartulary of Ramsey Abbey (Rolls Series, No. 79).
Vol. 35 & 36. Lists of the voyages of Martin Frobisher (Hakluyt's Voyages).

Exchequer Treasury of Receipt
Domestic Book.—Indexes and supplementary matter were printed by the Record Commission. Since then facsimiles of the text for each county have been issued.

Miscellaneous Books.
Vol. 16-55. Certificates of Musters. (See Letters and Papers of the Reign of Henry VIII.)
Vol. 69. Extents of Knights' Fees in the Honour of Richmond; printed in Gale's Registrum Honoris de Richmond.

Exchequer Augmentation Office
Vol. 495-515. Inventories of Church Goods. For details of those printed, see Myly et Bishop, Bibliographia Generalis des Inventaires Imprimés.

The following accounts of other collections of documents are necessarily less detailed.

Privy Council Office.—The registers of the Privy Council are still preserved in that office, with the exception of a few volumes which have strayed into other places. J. R. Dassen has edited for the Master of the Rolls a series of volumes containing The Acts of the Privy Council, 1482 to 1515, and The Acts of the Privy Council, 10 Rich. II.—33 Henry VIII., edited for the Record Commission by Sir N. Harris Nicolas, are from documents in the Cotton MSS. and from transcripts made by Rymer from documents in the Public Record Office.

India Office.—The records of the India Office are preserved there. Complete printed lists exist for the whole collection, and the following documents have been published: The First Letter Book of the East India Company, 1601-1613, edited by G. W. Forrest and W. Foster; Letters received by the East India Company from its Servants in the East, edited by F. C. Danvers and W. Foster (6 vols.). The records in India may be mentioned here. Each presidency and each province keeps its own; and this is the case also with the smaller subdivisions. No printed lists appear to exist for any of the collections. The following volumes have been published: Letters, Despatches and other Papers of the Foreign Department of the Government of India, 1772-85, edited by G. W. Forrest (3 vols., Calcutta); Bengal 1756-1757, edited by S. C. Hill (3 vols., 1906); and Old Fort William, edited by C. R. Wilson (3 vols., 1906-7).

Ireland.
The Public Record Office of Ireland was established in 1867 by the Act 30 & 31 Vict. c. 70, when the records of the various courts of law, all wills proved in Ireland, and certain financial records, were collected into one building. The State Paper Office of Ireland was established by the Act 29 & 30 Vict. c. 51, and the records of the Irish revenues are now preserved in the General Register House of Dublin Castle, whence the papers are only transferred to the Record Office by special order. The Deputy Keeper of the Irish Record Office publishes yearly reports with appendices. The most important collection is that of the Chancery papers, comprising warrants for the issue of letters under the Great Seal, Henry VIII., to Elizabeth, contained in Reports 7-9, 11-13, 15-18, with indices for each reign. A calendar of the Deeds of Church, Dublin, is contained in the 26th, 27th, 28th, 29th, and 30th Reports. Wills and Inventories of Dublin Castle are indexed under the names of the testators in the 26th and 30th Reports. The series of Proclamations by the lord lieutenant and council, and by the crown, which is among the records in the Record Tower at Dublin Castle, is contained in the 23rd and 24th Reports. Of the financial records very little has been published. In the 33rd Report there is a good account of the Books of the Treasury and Accounting Department from the reign of Henry VIII. Scattered entries from the Privy Rolls and the Rolls of the Irish Office are included in the 33rd and 35th-38th Reports. Before the establishment of the Record Office the Irish Record Commission published a Latin calendar of the Patent and Close Rolls from Henry II. to Henry VIII. Under the authority of the Master of the Rolls a calendar was published for the period Henry VIII. to Elizabeth, upon which some severe comments will be found in J. T. Gilbert's The History... of the Public Records.

An English calendar for the reign of James I. was published by the Record Commission; and a calendar for the years 18-25 Charles I., under the authority of the Master of the Rolls. Two large folio volumes for the years 30-38 were published by the Record Commission. The history and contents of this astounding work can be gathered from its introduction, and from an index to it in the 9th Report. Inquisitions post mortem and on attainders, for the provinces of Leinster and Munster, and the preliminary Inquisitions post mortem of Hibernia, are published in an abridged form in the Register Office.

Scotland.
The records of the kingdom are deposited in several places in Edinburgh. The principal repository is the General Register House, at present governed by the Act 42 & 43 Vict. c. 44. But certain records of the chancery and all the records of the court of teinds are in separate repositories. A general account of these records is given in M. Livingstone's Guide to the Public Records of Scotland deposited in D. 2. of the General Register House, Edinburgh, with appendices describing those contained in other repositories.

Privy Council.—The register of the Privy Council of Scotland from 1545 is in course of publication at the General Register House. Exchequer.—The Exchequer Rolls, corresponding to the Great Rolls of the English Exchequer, are being printed in full from 1324 at the General Register House; and the Exchequer Records of the Treasurer of Scotland from 1473 are being published at the same office.

Chancery.—The enrolments of letters issued under the Great Seal of Scotland are contained in two rolls and a series of volumes; The Record Commission printed these registers in full for the period 1366-1424; and the General Register House is continuing the publication in an abridged form.

Court of Chancery.—Only the enrolments of letters under the Great Seal of Scotland are transferred to the collection of the Record Office, the remainder are preserved in the court of chancery. The most important of these are the Returns to Chancery. To these the only printed means of reference is the Inquisitionum ad capellam Regis Romani in Scotia (16th and 17th centuries), published by the Record Commission.

Local Records.
To deal with the municipal and local records of Great Britain in any detail is quite impossible in this article. Fortunately the admirable work of C. Gross, entitled The Bibliography of Municipal History (Harvard Historical Studies), contains a complete account of the work done on municipal records up to 1897; while the Report of the Committee appointed to inquire into the existing arrangements for the collection and custody of local records (1902) affords a complete view of the questions dealt with by it.
Private Collections.—The publications of the Historical Manuscripts Commission are in most cases the only printed means of reference to private muniments. The 17th Report of the Commission contains an index to all the collections of papers so far dealt with by them.

With the rise of the Probate Act (20 & 21 Vict. c. 77) the proving of wills was under ecclesiastical jurisdiction, and the wills themselves were scattered among peculiar courts—courts of the various bishops, and the prerogative court of Canterbury. In 1852, passing of the act a general registry was established at Somerset House, to which were transferred all the wills of the prerogative court of Canterbury and of many of the other registries. But even at the present time there remains much confusion and uncertainty as to the place of deposit of the wills of any particular county, and of course the information on this point the inventor must refer to the Handbook to the Ancients Courts of Probate and Depozitories of Wills, by G. W. Marshall.

British Colonies.

For the British colonies the most important records, historically speaking, are the Colonial Office papers deposited in the Public Record Office, London; and those colonies which have published the records relating to their history have usually gone to that source. But there is in the Colonial Secretary’s office at Sydney a collection of records dating from 1789, which are included in the volumes published by that State. Cape Colony possesses records dating from 1652; G. McCall Theal, historian of the Colony, published in 1887 a series of volumes of documents drawn from the Public Record Office and other European sources. Canada has recently centralized its records, of which a large part so far consists of transcripts made in Europe. For an account see E. C. Burnett’s List of Manuscript Repositories, 1887. (See also Hohlbaum’s Archivistik des Europa’s, 1895.)

European Countries.

In dealing with Great Britain it seems desirable to give some account of publications dealing with the contents of the repository described. Under the heading of the article this will not be attempted. For the most part the books mentioned are in themselves bibliographies and guides, and do not contain even abstracts or descriptions of actual documents. It is scarcely necessary to explain that much of the following information is based on the work of Langlois and Stein, and in (Appendices) are given many lists and accounts of records.

Austria and Hungary.—The records of Austria-Hungary, Bohemia, and the other states under the same government, are still preserved locally. There are repositories of government records kept in each city or district, and in other large places of deposit. Even at Vienna there is nothing resembling the English Public Record Office; the Kaiserliches und kungenische Haus-, Hof- and Staatsarchiv contains the papers of the imperial family and the records of imperial administration and of that empire, but has little connection with the history of the Ministry of War. There is no complete inventory of all these records. At Budapest since 1875 have been collected the archives of Hungary, Transylvania, Croatia and the government of Fiume; for an account of the records in this and other Hungarian and Transylvanian repositories see Fr. Zimmermann’s Uber Archiv in Ungarn; ein Führer durch ungarische und siebenburgische Archive.

Belgium.—The records of Belgium are numerous, expensive and valuable. State Records comprise all those of the central governments of the modern kingdom, of the governments preceding it, and of the various states of such as Brabant, Flanders, Gueldres and Hainault out of which Belgium was formed. As the repository of the former part of these records is the central government in provincial repositories. Thus at Ghent are archives of the county of Flanders, at Liége of the princedom of that name and of the duchy of Limburg, at Mons of the county of Hainault, at Bruges of the county of West Flanders; at Namur, Arlon, Hasselt and Tournai are repositories of less importance: at the same time the repository at Brussels contains many records of the same kind as those in the provincial offices, and almost all those which have been formed from various collections in Belgium combined with records restored by the Austrian government and other acquisitions. Archives Provinciales, the records of provincial administrations since 1794, are placed in the chief towns of each province; each collection, which falls into three periods, French (1794-1814), Dutch (1814-1830) and Belgian.

Municipal Archives.—The most important are those of Antwerp, Bruges, Ghent, Malines, Mons, Tournai and Ypres. The best book of general bibliographical reference for Belgian records is Pierre Meert’s Bibliographie de l’histoire de Belgique.

DENMARK.—At Copenhagen there has been, since 1889, a central Record office (Rigsarkiv) containing all the previously existing collections of records, and receiving those of the various ministries and offices. There are also repositories there, and at Odense and Viborg, for local records, municipal and others. The central office is publishing a series of inventories of documents in its custody.

FRANCE.—The best general work is Les Archives de l’histoire de France, by Langlois and Stein. The administration of the records is attached to the Ministry of Public Instruction, acting through a commission and inspectors. The Armes de la République, in the Hôtel Souville at Paris, are divided into three sections, Historique, Administratif et Domanial, and Ministériel et Judiciaire, each containing subsections distinguished by letters or groups of letters. The classification is by subject, and the most valuable are the registers of patents, sales, and cabinets, e.g. the archives of the Trésor des Charms, the Parliament of Paris and the Cdtelet, represent real groups of records with a common history.

Archives des Ministères.—In theory the Archives Nationales should receive all government office records, except those in current use; actually several offices retain their own. Thus the Ministry of Foreign Affairs keeps its archives, divided into Correspondance politique et Mémoires et Documents: it also has, in series of Inventaire analytique des Archives du Ministre des Affaires étrangères, and Receaux des instructions données aux ambassadeurs et ministres de France depuis des traité de Westphalie jusqu’à la Résolution française. The Ministries of War and the Marine likewise possess their own archives, as do others.

Archives Départementales.—Each department possesses a special office for the custody of its records, which are in many cases of great importance, consisting partly of the records of the ancient provincial governments, private documents seized at the Revolution, muniments of religious houses, &c., and partly of documents presented after the Restoration. The records of these latter bodies, however, have been transferred to the Ministry of War and are in no way accessible. For a general view of the arrangement and contents of departmental repositories see Etat général par glands des archives départementales, ancien régime et période révolutionnaire (1905), and others. The general index is given in the Répertoire des Archives nationales, edited by J. H. Round, containing early monastic charters, is based on these.

GERMANY.—Unfortunately lists of German State archives (Gebäude Archivs) are not published. Repositories are very numerous: for their localities, see the Hand- und Adressebuch der deutschen Archive of C. A. H. Burkhardt (2nd ed., 1887). In the series of Inventaires analytique des Archives des Archives historiques nationales (Letters of Henrietta Maria, &c.) and partly from Archives Départementales. The Record Office Calendar of Documents, France, edited by J. H. Round, containing early monastic charters, is based on these.

Institutions.—For the publication of local societies see Manuel de bibliographie de l’histoire, by Ch. V. Langlois, (1901) p. 385 seq.

Archives Municipales et Communaules: the value of these arises largely from the fact that they have had an undisturbed history: a list of the collections exist in print. (See Langlois and Stein, op. cit. pp. 278-442.)

Archives Hospitalières form an important body of records, for the most part undisturbed. For their classification, and a list of the repositories of them, see Langlois and Stein, p. 443 seq.; the following are the most important: those at Paris, Orleans and Avignon, but the province of Strasbourg has been transferred to the same in the same work; note, however, that the archives of the Bastille are now in the Bibliothèque de l’Arsenal at Paris. There are in the English Public Record Office seventy-three volumes of transcripts from French archives: while from France, in the Archives du Roi, the Archives nationales, and the Archives de la République, there are a large number of records. The French have organized the nationale Archives historiques, and have collected there the records of the famous, e.g. the Grandes Chartes and the États-Généraux.

Lord Brougham’s letter to the editor of the Times (25.5.1860), expressing the hope that English students would visit and be enabled to use these records, will be found in the Times for the 26th May. There is an article on this archivology in the Encyclopaedia Britannica. Grundzüge der Geschichte, by Ströber, Wittenberg, Braun, and Junker, is a very valuable and authoritative guide to the archives of Mecklenburg and Pomerania. The chief authority on the archives of Prussia is Friedrich Deutsc. Archiw. Der Archivistik, 1897, by R. Hohlbaum’s Archivistik des Europa’s, 1895.)

The for the number of records of German towns reference may be made to the works already mentioned. Many of the towns, e.g. Cologne, publish volumes drawn from their archives, and even private libraries, e.g. those of A. M. Stein and of the Prussian Academy of Sciences. The alphabetical index of the leaves of the archives, and of the librarians of the nationale Archiv, is a work of great interest to English students is Konstantin Höhblum’s work upon the Hanse towns. The Record Office has a volume of transcripts from German archives.

AND.—There is one repository for each of the eleven states. That at the Hague, for south Holland, serves also as a central repository for the whole kingdom. This collection occupies a special building, and includes the records of Foreign Affairs, classed under the countries to which they relate, and certain documents acquired from the collection of Sir Thomas Phillips. There are many printed and manuscript lists, and access to the documents is easy. This is also the case with the other provincial archives, of which the most important are those at Arnhem,
Hertogenbosch, Groningen, Haarlem, Maastricht, Middelburg and Utrecht.

Town archives are for the most part well preserved. Printed inventories generally exist, and in some cases, e.g. at Dosselburg, the archives of the Utrecht University contain the relations between the
Hanse and England in the 14th century.

Dutch repositories have no administrative inter-connexion. Each archivist reports yearly to the archivist-in-chief of the
H. E. van der Hoop, who is the keeper of the Archives. His
Vestigia ovii Archivii have been printed.

The English Public Record Office has four volumes of transcripts from
Dutch archives.

ITALY.—The administration of the public records of the kingdom
is the duty of the Minister of the Interior, for which office Sigis-
Vasio published (1883) his Relazione sugli archivi di stato italiani.
There are seventeen repositories, representing the ancient divisions
of the kingdom. The most important are the following:

Florence, contains the foreign correspondence of
the dukes of Tuscany and the Florentine republic.

Genoa, records of the republic.

Milan, records of the duchy, in particular the registers called
L’Archivio Pamorugano.

Modena, records of the family of Este.

Naples, in particular the Cancelleria Angioina; records of the
Angevin kings of Naples, containing documents relative to their
estates in Provence, Savoy, and elsewhere, for a
bibliographical account of which see Le Archives Angéne de
Naples, études sur les registres du Roi Charles Ier, by Paul Durrieu.
Naples also possesses the important Archivio Farnesiano, mainly
records of the duke of Parma, brought thither by Charles I. of Bourbon on
his return to Naples in 1735.

Palermo, the records of the island of Sicily.

Rome, the most important records of the Archivio di Stato are
those relating to the papal government which were not transferred
to the Vatican in 1870.

Turin, the archives of the house of Savoy, especially the letters
sent from foreign courts, a series of very important reports.

Venice, the convent dei Frati contains probably the most
important documents of the Province of Venice and elsewhere, for a
bibliographical account of which see Le Archives de Venetia
Cavendish Bentinck, and H. F. Brown have edited many of the
principal documents relating to England in the State Papers:
Venetian (Record Office), which are still in progress. The
Record Office has many unprinted volumes of
archival documents of Napoleonic period from Venetian archives, mostly the reports and correspondence of
ambassadors, together with Rawdon Brown’s large collection of
similar materials, mainly originals or early copies (see Report 46).

Archivio Segreto, which may be divided into two heads, the original
Archivio Segreto and the archives added to it from Avignon, from
the castle of St Angelo and from special offices such as the Consistory,
dicta Apositolica, Rota, Secreta Bressus, Signatura Gratiae,
Fenestella and Master of the Ceremonies. The records of the
congregations of the Index, the Holy Office and the Propaganda
are not usually accessible to students.

Since 1881 the importance of the archives has attracted to Rome
many bands of students. Most European governments have
arranged for the publication of records dealing with their own
countries. The classes of documents that have received most
attention are the Regesta, or registers of bulls and briefs, issued by
the Holy See. The H. F. Brown, and J. A. O’Neill have
published a number of the Regestas. In London has published one volume of
Pettines, 1342-1417, and a Calendar from the Regesta, which covers the period 1198-1431.

The French government is publishing a complete Calendar of the
Regestas. The French archives are the English Public Record Office one hundred and sixty-two volumes of transcripts from
the Vatican archives arranged in two series.

Norway.—The records of Norway are preserved at Christiania,
and include a collection of papers of Christian II, king of Denmark.
For the most part, these documents have been published by Lange and Unger (1849-1851); and Norske Rigsekurator
Telecles i Oddag, dealing with the 16th and 17th centuries.

Portugal.—Portuguese royal records are in the monastery of
São Bento at Lisbon. The collection suffered much during the
earthquake of 1755. It includes the registers of the Chancery
since the 13th century, and a large number of documents subsidiary
to them. In addition to this repository there are collections at
the various ministries; from the records of the Ministry for Foreign
Affairs, Borges de Castro, and afterwards Judice Biker, published their
Collection dos Tratados . . . entre a Corona de Portugal and as mais potentas. There are three volumes of transcripts from
Portuguese records in the English Public Record Office.

Spain.—The nearest approach to a central Record Office for
Spain is the Archivo General Central, established by a royal ordinance of
1898 at Alcalá de Henares, near Madrid. The collection there consists of the records of
the papal government and the archbishops of
Rome, Palermo, Venice, and Sicily.

Since 1889 an important series of American records have been
published by the Archivo General of Madrid: the records of the
castle of Segovia, the castle of Segovia and the castle of the
duke of Medina Sidonia, and other important documents of the
papal government in Spain.

The archives have not yet been centralized, and large
collections exist at the various ministries. The most important
collections, however, are the Royal Archives (Riguarchiv), pre-
severed by the government of the Spanish Empire, but
published at Madrid and elsewhere; and the documents of
the papal government in Spain are published under the
Archiva General. The Archivo General is now in the hands of
the government of Spain, and the documents are being
published under the direction of the Archivo General. The
publications have been based on these: there are for instance an
inventory, Middelalén von Svenska Riggarchivet; a work bearing
on general history, handling rörande Scandinavisk historia; a work bearing
generally on Russian history, Petrogradsche and Landschat
Zürich, by P. Schweitzer and E. Escher (1889-1892).

There are in the English Public Record Office five volumes of
transcripts from the Spanish Archives.

UNITED STATES OF AMERICA

The records, among which transcripts made in England, France,
and Holland held an important place, may be divided into:
Federal, kept at Washington; those in private collections; and State Records at the
various state capitals. The publication and care of these
are often the work of private bodies subsidized or recognized by
government. Thus, although Federal archives are now centralized
in the hands of the archivist of the Library of Congress, which is the
Library of Congress, which is the official depository of the Federal Government
and of the Archives Commission of the Historical Society.

The same association explores private collections through its
Historical Manuscripts Commission; and several societies publish
State Records, and State Archives. The Library of Congress publishes
American and European documents relating to their history;
and mention must be made of the large series of American Archives
and State Records published from 1832 onwards by
Congress.
RECORDE—RECORDER

The best guide for Federal records is the work of Leland and Valentine; for a general bibliographical work of reference see E. C. Burnett’s List of Printed Guides . . . (Historical MSS, Commission Report, 1897).

EXTRAVAGANZA

In various ways records are apt to wander from their proper custody and to lose their legal character. But in spite of this loss the historian is bound to pursue them either into the hands of private collectors or on to the shelves of some museum. No attempt can be made however to trace the many various collections of records, known to have been formed during the lifetime of the recorders by various public and private individuals, the records themselves, or in some cases their editors, or somewhere for the entertainment or instruction of the public. Even among English libraries it must be sufficient to mention the British Museum as the principal destination of wandering records. Of the collections in that library the most important to the student of records are the Cottonian, the Harleian and the Additioinal catalogues of record material. There is also a Catalogue of the Additional, catalogued from time to time as fresh matter accrues; the Egerton, catalogued with the Additional; the Sloane and the Stone, both catalogued. No distinction is made between documents which must have been technically "records," and others. The whole collection is divided technically into Manuscripts, by which are meant volumes, and Charters and Rolls, meaning detached documents. To the latter class an Index locorum, compiled by H. F. Ellis and F. B. Bickley, has been printed. (C. G. C.)

RECORDE, ROBERT (c. 1510–1558), Welsh physician and mathematician, was descended from a respectable family of Tenby in Wales. He entered the university of Oxford about 1525, and was elected fellow of All Souls’ College in 1531. Having adopted medicine as a profession, he went to Cambridge, where he took his degree of Bachelor of Medicine in 1545. He returned to Oxford, where he publicly taught mathematics, as he had done prior to his going to Cambridge. It appears that he afterwards went to London, and acted as physician to Edward VI. and to Queen Mary, to whom some of his books are dedicated. He died in the King’s Bench prison, Southwark, where he was confined for debt, in 1558.

Reorde published several works upon mathematical subjects, chiefly in the form of dialogue between master and scholar, viz.:—

1. The Grounde of Artes, teaching the Worke and Practise of Arithmeticke, both in whole numbers and fractions (1550).
2. The Pathway to Knowledge, containing the use of Instrumente Geometrical and Astronomical, and also for Projection of Platoes (London, 1551).
3. The Castle of Knowledge, containing the Explanation of the Sphere both Celestiall and Materiall, &c. (London, 1556).
4. The Whansone of Witte, which is the second part of Arithmetike, containing the Extraction of Roots, the Cositake Practise, with the Rules of Equation, and the Workes of Surde Numbers (London, 1557). This was the first English book on algebra. He wrote also a medical work, The Urinal of Physic (1541), which is only reprinted. Sherburne states that Recorde also published Cosmographiae isagoge, and that he wrote a book De Arte facienda Horologium and another De Uso Globorum et de Statu temporum. Recorde’s chief contributions to the progress of algebra were in the way of systematizing its notation (see ALGEBRA, History).

RECORDE, in its original sense, one who sets down or records. Hence applied to a person with legal knowledge who was appointed by the mayor and aldermen to "record" or keep in mind the proceedings of their court, as well as the customs of the city. The word is now chiefly used of the principal legal officer of a city or borough having a separate court of quarter sessions. He must be a barrister of five years’ standing, appointed by the crown and holding office during good behaviour, and receiving "such yearly salary, not exceeding that stated in the petition on which the grant of a separate court of quarter sessions was made," as the sovereign directs (Municipal Corporations Act 1882, s. 193). The recorder holds, once in every quarter of a year, or oftener, if he thinks fit, a court of quarter sessions in and for the borough. He is sole judge of the court, "having cognizance of all crimes, offences, and matters cognizable by courts of quarter sessions from and after the 28th of May, 1835," except that he may not allow any oracle borough rate, or grant licences (s. 165). He is not eligible to serve in parliament for the borough, or to be an alderman or councillor, or stipendiary magistrate for the borough, though he may be revising barrister and is eligible to serve in Parliament except for the borough. He may be appointed recorder for two or more boroughs conjointly. He may, in case of sickness or unavoidable absence, appoint in writing a barrister of five years’ standing to act as deputy recorder for him. A recorder is ex officio a justice for the borough.

The recorder of London is judge of the lord mayor’s court, and one of the commissioners of the central criminal court. His salary is £400 a year. He is appointed by the lord mayor and aldermen, but by the Local Government Act 1888, s. 42, sub-s. 14, after the vacancy next after the beginning of the act, no recorder may exercise any judicial function unless he is appointed by the sovereign to exercise such function. See Quarter Sessions, Court of.

RECORDE, Fipple Flute or English Flute (Fr. flûte—à-bec, flûte douce, flûte anglaise or flûte à neuf trous; Ger. Block- oder Flockflöte, Schnabelflöte, Langflöte; Ital. flauto dolce, flauto diritto), a medieval flute, blown by means of a whistle mouthpiece and held vertically in front of the performer like a clarinet. The recorder only survives in the now almost obsolete flagelet and in the so-called penny-whistle. The recorder consisted of a wooden tube, which was at first cylindrical or nearly so, but became, as the instrument developed and improved, an inverted cone. The whistle mouthpiece has been traced in almost prehistoric times in Egypt and other Oriental countries. The principle of the whistle mouthpiece is based on that of the simplest flutes without embouchure, like the Egyptian simple flute, and modern reed instruments. In order to facilitate the production of sound, the air current, instead of being directed through ambient air to the sharp edge of the tube (or the lateral embouchure in the modern flute), is blown through a chink directly into a narrow channel. This channel is so constructed within the mouthpiece that the stream of air impinges with force against the sharp edge of a lip or fipple cut into the pipe below the channel. This throws the air current into the state of vibration required in order to generate sound-waves in the main column of air within the tube. The inverted cone of the bore has the effect of softening the tone of the recorder still further, earning for it the name of flûte douce. Being so easy to play, the recorder always enjoyed great popularity in all countries until the greater possibilities of the transverse flute turned the tide against it. The want of character which distinguishes the timbre of the whistle-flute is due to the paucity of harmonic overtones in the clang. The recorder had seven holes in front and one at the back for the thumb. As long as the tube was made in one piece the lowest hole stopped by the little finger was generally made in duplicate to serve equally well for right- and left-handed players, the unused hole being sealed up with wax. When the pipe was made of two pieces, the recorder could have six holes, and the third hole, which could be sealed up by a plug without disturbing the octave and even the first two harmonics (i.e. the twelfth and second octave). The holes produced the diatonic scale, and by means of harmonics and cross-fingering the second and part of a third octave were obtained.

The recorder is described and figured by Sebastian Virdung, Martin Agricola and Ottmar Luscinius in the 16th century, and by Michael Praetorius and Marin Mesernie in the 17th century. Praetorius mentions eight different sizes ranging from the smallest flute two octaves above the cornetto to the great bass. The lowest notes of the large flutes were provided with keys enclosed in perforated wooden or brass cases, which served to protect the mechanism, as yet somewhat primitive; the keys usually had double touch pieces to suit right- or left-hand players.

There are at least two fine sets of recorders extant: one is preserved in the Germanisches Museum at Nuremberg, consisting of eight flutes in a case and dating from the 17th century; the other is the Chester set of four 18th-century instruments, which are fully described and illustrated in a paper by Joseph C. Bridge.

The recorder has been immortalized by Shakespeare in the famous scene in Hamlet (II, 3), which has been treated from the musical point of view in an excellent and carefully written article by Christopher Welch, the author of an equally valuable paper, "The Literature of the Recorder." The small whistle-pipe used to accompany the tabor (Fr. galoubet; Ger. Kaminpijp, galoubet), which had but three holes, belongs to the same family as the recorder, but from its association with the tabor it acquired distinctive characteristics (see PIPE AND TABOR).

—K. S.)

RECTOR—RED-BREAST

RECTOR (Lat. for "ruler," "guide" &c., from regere, "rule") is a title given to the bearers of certain ecclesiastical and academic offices. In the Roman empire, after Constantine, the title rector was borne by governors of provinces subordinate to the prefects or exarchs. In the middle ages it was given to certain secular officials, e.g. the podestas of some Italian towns, but more especially to the heads of the universities, the representatives and rulers of the universitas magistrorum et scholarum, elected usually for a very short time. After the humanistic movement of the Renaissance the style rector was also given to the chief masters of schools containing several classes, and in some parts of Germany (e.g. Saxony, Württemberg) it is still thus used instead of the more modern title of Director. Rector is also still the title of the heads of the Scottish universities (Lord Rector), who are elected for three years, and of the German universities (Rector Magnificus), in which the office is held for a year by a representative of each faculty in turn. In those German universities where the rectorship is held by the sovereign (Rector Magnificus), the acting head is known as Prorector. "Rector" is also the title of the heads of Exeter and Lincoln Colleges, Oxford. The heads of all Jesuit colleges are "rectors." As an ecclesiastical title rector was once loosely used for rulers of the Church generally, whether bishops, abbots or parish priests (see Du Cange, Recolte ecclesiastum). The Recoltes Apostolici Patrimonii were clerics of the Roman Curia charged with the duty of looking after the interests of the patrimony of St Peter. The ecclesiastical title rector, however, became ultimately confined in certain parts of Europe (Poland, Spain and notably England) to the office of a priest having a cure of souls. In its English use it is thus synonymous with "curate" in the sense used in the Prayer Book. In the middle ages a large number of rectories were held by religious houses, which drew the bulk of the tithes and appointed vicars to do the work. Hence the modern distinction in England between rectors and vicars. A rector is incumbent of a benefice never held under a monastery, and he receives all the tithes; a vicar (i.e. of an ancient benefice) draws only such tithes as were left to the benefice by the religious house which held it. On the suppression of the monasteries the "great tithes" were often bestowed by the crown on laymen, who, as owning the rectorial tithes, were and are known as "lay rectors." It follows that, rectories being usually richer than vicarages, the style of "rector" is in England slightly more dignified than that of "vicar." In the American Protestant Episcopal Church the incumbents of churches are called rectors.

RECUSSANT (from Lat. recusare, to refuse), the name, in English history, given in the 16th and 17th centuries to those persons who persisted in refusing to attend the services of the English Church, and particularly to those of the Roman Catholic faith (see ROMAN-CATHOLIC CHURCH, § English Law).

REDAN, in fortification, a work of V-shape presenting a salient angle towards the expected attack. The gorge (rear) of a redan is open. When unsupported by other works, it has the disadvantage that its fire is divergent and but few guns can be brought to bear directly towards the front. Further, both its faces are usually open to enfilade. Redans were therefore almost always used in conjunction with other works, one of the most common forms being the "lines of redans" used as field works. These consisted of lengths of plain trenches facing the front, with redans at intervals along the line. In the present day the term redan is loosely applied to works merely possessing saliency, as in the case of the celebrated bastions Nos. 3 and 2 at Sevastopol in 1854-55, usually called the "Redan" and "Little Redan" respectively (see CRIMEAN WAR). The "Redan" was a large work of irregular outline, generally resembling a redan, but having the salient angle blunted or rounded off and the side faces broken into several minor fronts so as to obtain a field of fire in many directions. (See Fortification and Siegecraft.)

RED BANK, a borough of Monmouth county, New Jersey, U.S.A., on an estuary known as Navesink river, at the head of navigation, about 6 m. W. of the Atlantic Ocean, and about 25 m. S. of New York City. Pop. (1900) 6253; (1910) 7298. Red Bank is served by the Central of New Jersey and the Pennsylvania railways, and by steamboats to New York, and is connected with the neighbouring towns by electric lines. It is a residential suburb of New York City and a summer resort. In the winter ice-boating is a popular amusement, and Red Bank has fish and oyster industries of some importance.

The name Red Bank was applied to this locality as early as 1734, and in 1781 there were several buildings within the limits of the present borough. Red Bank was incorporated as a town in 1870 and became a borough in 1900. Near Red Bank was established in 1843 the North American phalanx, a Fourierite community, with a capital of about $8000 and 112 members, on about 673 acres; it was financially the most successful and the longest lived of the Fourierist phalansteries in America, but broke up in 1855 because of internal dissensions, following a fire which destroyed the mills.

RED-BREAST, one of the most striking birds, and perhaps the favourite among English birds because of its pleasing colour, its sagacity and fearlessness of man, and its cheerful song, even in winter. In July and August the hedgerows of the southern counties of England are beset with red-breasts, not in flocks, but each individual keeping its own distance from the next—all, however, on their way to cross the Channel. On the European continent the migration is still more marked, and the redbreast on its autumnal and vernal passages is the object of bird-catchers, since its value as a delicacy has long been recognized. Even those red-breasts which stay in Britain during the winter are subject to a migratory movement. The first sharp frost makes them change their habitat, and a heavy fall of snow drives them towards the homesteads for food. The redbreast exhibits a curious uncertainty of temperament in regard to its nesting habits. At times it will place the utmost confidence in man, and at times show the greatest jealousy. The nest is usually built of moss and dead leaves, with a moderate lining of hair. In this it is laid from five to seven white eggs, sprinkled or blotched with light red.

Besides the British Islands, the red-breast (Motacilla rubecula of Linnaeus and the Erithacus rubecula of modern authors) is generally dispersed over the continent of Europe, and is in winter found in the oases of the Sahara. Its eastern limits are not well determined. In northern Persia it is replaced by a nearly allied form, Erithacus hircanus, distinguishable by its 

1 The borough of Red Bank should be distinguished from a place of the same name in Gloucester county, New Jersey, about 6 m. below Camden, on the Delaware river, nearly opposite the mouth of the Schuykill river, which was the site of Fort Mercer in the American Revolution. It was held by the British under Col. Christopher Greene (1727-1781), was unsuccessfully attacked by a force of about 2500 men, mostly Hessians, under Col. Carlo Emilio von Donop, the Hessians losing about 400 men, including Donop, who was mortally wounded.

2 English colonists in distant lands have applied the common nickname of the redbreast to other birds that are not immediately allied to it. The ordinary "robin" of North America is a thrush, Turdus migratorius (see fieldfare), and one of the bluebirds of the same continent, Stilis stilis, is in ordinary speech the blue "robin"; the Australian and Pacific "robins" of the genus Petroica are of doubtful affinity and have not all even the red breast; the Cape "robin" is Cossypha caffra, the Indian "robin" Thamnophilus and the New Zealand "robin" Miro.

3 It is a very old saying that Unum altum est genere non aliis erithaca. One bush does not harbour two red-breasts.
more ruddy hues, while in northern China and Japan another species, *E. akahige*, is found of which the sexes differ somewhat in plumage—the cock having a blackish band below his red breast and greyish-black flanks, while the hen closely resembles the familiar British species—but both cock and hen have the tail of chestnut-red. The genus *Erithacus*, as well as that containing the other birds to which the name "robin" has been applied, with the doubtful exception of *Petronia*, belong to the sub-family Turdinae of the thrushes (q.v.).

**REDCAR**, a watering-place in the Cleveland parliamentary division of the North Riding of Yorkshire, England, 8 m. N.E. of Middlesbrough, on a branch of the North-Eastern railway. Pop. of urban district (including the township of Coatham, 1901) 7605. Its long range of firm sands from Tees mouth to Saltburn, a distance of 10 m., has made it a popular summer resort. Race meetings are held here on Whit Monday and Tuesday, and in August. Redcar is close to the Cleveland iron-working district of which the centre is Middlesbrough, and is in great favour with the large industrial population of that district.

**REDDITCH**, a town in the eastern parliamentary division of Worcestershire, England, situated on an eminence near the Warwickshire border, 15½ m. S. of Birmingham by the Midland railway. Pop. of urban district (1901) 13,492. It is the centre of a district producing needles and fish-hooks. There are also motor-engineering works. The town possesses a literary and scientific institute (1830). In the modern church of St Stephen (1854) are preserved tiles from the former Cistercian abbey of Bordesley, founded in 1138, of which the site may be traced at Bordesley Park, 2 m. N.

**REDESDALE, JOHN FREEMAN-MITFORD, BARON (1748–1830)**, English lawyer and politician, younger son of John Mitford (d. 1761) and brother of the historian William Mitford, was born in London on the 18th of August 1748. Having become a barrister of the Inner Temple in 1777, he wrote *A Treatise on the Pleadings in Suits in the Court of Chancery by English Bill*, a work of great value, which has been reprinted several times in England and America. In 1788 Mitford became member of parliament for the borough of Bedalston in Devon and in 1791 he introduced the important bill for the relief of Roman Catholics, which was passed into law. In 1793 he succeeded Sir John Scott, afterwards Lord Eldon, as solicitor-general for England, becoming attorney-general six years later, when he was returned to parliament as member for East Looe, in Cornwall. In February 1801 Sir John Mitford (as he was now) was chosen speaker of the House of Commons. Exactly a year later, he was appointed lord chancellor of Ireland and was created a peer of the United Kingdom as Baron Redesdale. Being an outspoken opponent of Roman Catholic emancipation, Redesdale was unpopular in Ireland. In February 1806 he was dismissed from the commission of the ministry of Fox and Lord Grenville. Although Redesdale declined to return to official life, he was an active member of the House of Lords both on its political and its judicial sides. In 1813 he secured the passing of acts for the relief of insolvent debtors, and later he was an opponent of the repeal of the Test and Corporation Acts and of other popular measures of reform. Redesdale, who was a fellow of the Royal Society and a member of three commissions on the public records, died on the 10th of January 1830. In 1803 he married Frances (d. 1817), daughter of John, 2nd earl of Egmont. He took the additional name of Freeman in 1809 on succeeding to the estates of Thomas Edwards Freeman.

His only son, John Thomas Freeman Mitford (1805–1886), succeeded to the title. In 1821 he was chosen chairman of committees in the House of Lords, a position which he retained until his death, and in 1877 he was created earl of Redesdale. His chief interest was reserved for ecclesiastical questions, and he won some repute as a Protestant controversialist. He assisted to revive Convocation in 1853; was an active opponent of the disestablishment of the Irish Church; and engaged in controversy with Cardinal Manning on the subject of communion in both kinds. On his death, on the 2nd of May 1886, his titles became extinct. He wrote *Thoughts on English Prosody and Translations from Horace*, and *Further Thoughts on English Prosody* (Oxford, 1859), in addition to various pamphlets on ecclesiastical topics.

The earl bequeathed his estates to his kinsman, Algernon Bertram Freeman-Mitford (b. 1837), a great-grandson of William Mitford. He had been in the diplomatic service from 1858 to 1873, and had been secretary to the Office of Works from 1874 to 1886. From 1892 to 1895 he was member of parliament for the Stratford-on-Avon division of Warwickshire, and he was created Baron Redesdale in 1902. He was well known for his writings on Japan, *Tales of Old Japan* (1871), *The Attaché at Peking* (1900), &c.

**REDFERN, a municipality of Cumberland county, New South Wales, Australia, adjoining the city of Sydney on the S.S.W. Pop. (1901) 24,282. It is a busy manufacturing centre, having numerous ironworks, coach factories, boot factories, printing works, iron and brass foundries, soap factories and extensive railway works.**

**REDGRAVE, RICHARD (1804–1888)**, English artist, was born at Pimlico on the 30th of April 1804, and worked at first as a designer. He became a student in the Royal Academy Schools in 1826, and was elected an Associate in 1840 and an Academician in 1851 (retired, 1882). His "Gulliver on the Farmer's Table" (1837) made his reputation as a painter. He began in 1847 a connexion with the Government Art Schools which lasted for a long term of years, and among other posts he held those of inspector-general of art in the Science and Art Department, and art director of the South Kensington Museum. He was greatly instrumental in the establishment of this institution, and he claimed the credit of having secured the Sheepshanks and Ellison gifts of important works of art. He was also surveyor of the royal pictures. He was offered, but declined, a knighthood in 1860. Redgrave was an assiduous painter of landscapes and genre: his best pictures being "Country Cousins" (1848) and "The Return of Olivia" (1848), both in the national collection, "The Sempstress" (1844), "Well Spring in the Forest" (1865). He died on the 14th of December 1888.

See the *Memoir* by F. M. Redgrave, 1891.

**REDLANDS, a city of San Bernardino county, in southern California, U.S.A., 67 m. (by rail) E. of Los Angeles. Pop. (1900) 4797; (1910) 10,449. It is served by the Southern Pacific and the Atchison, Topeka & Santa Fé railways and by interurban electric lines. The city lies at an altitude of 1350–1600 ft. at the eastern end of the San Bernardino Valley, surrounded on three sides by mountains. To the east Grayback (11,725 ft.) and San Bernardino (11,060 ft.), to the south-east San Jacinto (10,805 ft.), and to the north-west Cajon Pass (4191 ft.) and San Antonio, of Old Baldy (10,142 ft.), are conspicuous landmarks. The city is a well-known tourist and health resort, with beautiful drives. Canyon Crest Park (Smiley Heights) contains about 200 acres, and Prospect Park 50 acres. The city has the A. K. Smiley Public Library, the gift of A. K. Smiley, and is the seat of the University of Redlands (Baptist; co-educational), incorporated in 1907 and opened in 1909. Redlands is one of the most famous orange-growing and shipping centres of California; it also ships other citrus fruits, olive oil, barley, wheat and stone. Olive oil and jam, marmalade and preserved fruits are manufactured. There are electric power plants in the mountains (three in Mill Creek Canyon and two in Santa Ana Canyon). A settlement called Lugonia was established within the limits of the present city in 1874, but Redlands dates from 1887, when it was settled by people from New England, and was chartered as a city.

**REDMUND, JOHN EDWARD (1857– ), Irish politician, son of W. A. Redmond, M.P., was born at Waterford in 1857.**
He was educated at Trinity College, Dublin, and was called to the bar at Gray's Inn in 1886, and subsequently to the Irish bar, though he never practised. He was a clerk in the vote office of the House of Commons before he entered parliament in 1881 as member for New Ross. From 1885 to 1891 he represented North Wexford. As party whip he rendered great service to the Irish members by his thorough grasp of the procedure of the House. At the time of the rupture of the Irish party consequent on the Parnell scandals, Redmond was the most eloquent member of the minority who continued to recognize his leadership, and in 1891 he became the accredited leader of the Parnellites. In 1900 the two Nationalist parties were amalgamated under his leadership. He contested Cork unsuccessfully in 1891, but was elected for Waterford, where he was re-elected in 1906. (For the political events under his leadership of the Irish parliamentary party up to 1910, see Ireland: History; English History and allied articles.)

**REDON**, a town of western France, capital of an arrondissement in the department of Ille-et-Vilaine, 45 m. S.S.W. of Rennes by rail. Pop. (1900) 5170. Redon is situated on the right bank of the Vilaine, above the confluence of the Oust and on the canal from Nantes to Brest. The Church of St Sauveur, formerly belonging to an abbey, has a Romanesque central tower, square in form but with rounded angles. A fine tower of the 14th century with a stone spire stands isolated from the church, from which it was separated owing to the destruction of part of the nave by fire in 1782. The choir, with ambulatory and radiating chapels, forms one of the most remarkable examples of 13th-century architecture in Brittany. The abbey has been converted into an ecclesiastical college. Some 16th-century timbered houses have interesting carvings. The industries include the manufacture of emery and polish, agricultural implements and boat-building, tanning, brewing and flour-milling. The port is accessible at high tides for vessels of 600 to 700 tons. Redon grew up round a monastery founded in the first half of the 9th century. In the 14th century Jean de Tréf, one of the abbots, surrounded the town with walls, of which a remnant is still to be seen.

**REDONDA**, an island in the British West Indies. It is a dependency of Antigua, and lies 25 m. S.W. of it, in 25° 6' N. and 61° 35' W. Pop. (1901) 120. It is a rocky mountain, rising abruptly from the sea to a height of 1000 ft., and has an area of ¾ sq. m. It is valuable for its phosphate of alumina (discovered in 1865), of which 7000 tons are exported every year to the United States.

**REDONDELA**, a town of north-western Spain, in the province of Pontevedra; 7 m. N.E. of Vigo, in a bend of the Vigo estuary, and at the junction of the Tuy-Vigo and Vigo-Pontevedra railways. Pop. (1900) 10,843. The river is only accessible for small coasting vessels; it is the headquarters of a prosperous fishing industry. In the neighbourhood are ruins of several medieval castles, and the fine hall of the Marquess Vega de Armiño.

**REDUT** or **redoute**, from Med. Lat. *reductus*, a place of retreat, refuge, reduct, lead back, retire; the intrusive b is due to the O. Fr. *reduhter*, to fear, Lat. *dubitare*, to doubt), a term in fortification for a small closed work of plain trace, generally used in conjunction with lines of infantry trenches (see Fortification andSiegecraft). The term "reduit" (Fr. *réduit*), often confused with "redoubt," is only used for a keep or interior refuge for the Garrison of a larger work, corresponding, on a small scale, to the citadel of a fortress.

**RED RIVER**, the name of two American rivers, one emptying into the Mississippi near its mouth, and the other emptying into Lake Winnipeg.

1. The Red River, sometimes called the Red River of Louisiana, is the southernmost of the large tributaries of the Mississippi. It rises in northern Texas, in the northern part of the Staked Plains, or Llano Estacado, flows E. by S. in Texas, between Texas and Oklahoma, and to Fulton, in south-western Arkansas, there turns S.E. and continues in a general south-easterly direction through Louisiana to the bank of the Mississippi, where it discharges partly into the Mississippi and partly into the Atchafalaya. Its length is estimated at 1200 m. or more; its drainage basin has an area of at least 90,000 sq. m.; and its discharge ranges from 3500 cub. ft. to 180,000 cub. ft. per second. It is somewhat saline in its upper course, and in its middle and lower course is laden with a reddish silt from which it takes its name. From an elevation on the Staked Plains of about 2450 ft., the river plunges into a canyon which is about 60 m. long and has nearly perpendicular walls of sandstone and gypsum formation 500 to 800 ft. high. Immediately below the canyon the river spreads out over a broad and sandy bed and flows for about 500 m. through a semi-arid plain. It narrows on entering the alluvial bottom lands, through which it pursues a sluggish and meandering course for the last 600 m. At high stages, from December to June, it is continually shifting its channel in this part of its course, by eroding one bank and making deposits on the other, and as the upper portion is densely wooded the falling trees, unless removed, become an obstruction to navigation. In 1828 the trees which the river had felled formed the great "Red River raft" extending from Loggy Bayou, 65 m. below Shreveport, Louisiana, to Hurricane Bluffs, 27 m. above Shreveport. Congress began in that year to make appropriations for the removal of the raft, and by 1841 Henry M. Shreve had opened a channel. The river was neglected from 1857 to 1872 and another raft, 32 m. in length, formed above Shreveport. A channel was opened through this in 1872-73, and the complete removal of the obstructions a few years later so improved the drainage that a large tract of waste land was reclaimed. In its course through Louisiana the river has built up a flood-plain with silt deposits more rapidly than its tributaries, with the result that numerous lakes and bayous have been formed on either side, and Cypress Bayou was so flooded that boats plied between Shreveport, Louisiana and Jefferson, Texas, 45 m. apart; but with the improvement of the river these lakes have become shallow or dry. For the improvement of navigation here not only the removal of snags is necessary, but there must be dredging, closure of outlets, building of levees to narrow and deepen the channel, and revetment works to protect the banks. The cost of these works has been great (up to July 1900 more than $2,350,000 below Fulton, Arkansas, and more than $215,000 above Fulton), but they have rendered the river navigable, except at very low stages, by vessels drawing 3 ft. of water from its mouth to Fulton, Arkansas, a distance of 508-6 m., and at the highest stages, in March and April, it is navigable to Denison, Texas, 202 m. farther up. The Ouachita and Black (one river), which is the principal tributary of the Red, joins it near its mouth and is navigable at high stages to Arkadelphia, Arkansas; and in 1910 a system of nine locks with movable dams was under construction by the Federal government for the purpose of securing a channel 6½ ft. deep at all stages to a point 10 m. above Camden, Arkansas, a distance of 360 m.

During the Civil War, in March and April 1864, Major-General Nathaniel P. Banks conducted a combined military and naval expedition up the Red River in an attempt to open a Federal highway to Texas, but on the 8th of April the vanguard of his army was repulsed with heavy loss at Sabine Cross-Roads by the Confederates under Lieutenant-General Richard Taylor and the expedition was abandoned; the gunboats commanded by D. D. Porter were held above Alexandria by the lowness of the river, but it was flooded by a hurriedly built dam, and they escaped.

See R. B. Marcy and G. B. McClellan, *Exploration of the Red River of Louisiana* (Washington, 1853), and the annual Reports of the Chief of Engineers of the U.S. Army.

2. The Red river, commonly called the Red River of the North, rises in the lake region of western Minnesota, not far from the headwaters of the Mississippi, flows north between Minnesota and North Dakota, continues northward through the Canadian province of Manitoba, and discharges into Lake Winnipeg. It has cut a gorge 20–50 ft. deep through clay deposits through—

*The range between low water and high water at Fulton is 35–65 ft.*
RED RIVER SETTLEMENT—RED SEA

out the greater part of its course; it drains a region that is famous for the production of wheat; and much water power has been developed on its tributaries. The United States government has improved its channel from the international boundary to Breckenridge, Minnesota, a distance of 305.5 m., and occasionally the water reaches a height which permits small steamboats to ascend its S.W. branch to Lake Traverse and from there to descend the Minnesota river to the Mississippi.

RED RIVER SETTLEMENT, a Scottish colony founded in 1811 near the present city of Winnipeg by a philanthropic Scottish nobleman, Lord Selkirk, who at that time controlled the Hudson’s Bay Company. Quarrels soon arose with the French and half-breed employes of the North-West Fur Company, and were fostered by its officials. On June 19, 1816, in a fight between the rivals, Governor Semple of the Hudson’s Bay Company and twenty of his twenty-seven attendants were killed, an affair known as the Battle of Seven Oaks. New settlers were sent by Selkirk, and founded the village of Killdeer, now part of Winnipeg. In 1817 the Red River settlement was united, and in 1836 repurchased from Selkirk’s heirs all rights to the territory. In 1821 and in 1835 two forts, known as Lower and Upper Fort Garry, were built to command the junction of the Red and Assiniboine rivers, and around them grew up a mixed population of Scots, French and Indians. The purchase in 1869 of the territorial rights of the Company by the Dominion of Canada led to a rebellion, and the setting up of a provisional government under Louis Riel, which was dispersed by a force of British regulars under Colonel (later Lord) Wolseley.

See Canada (History); also George Bryce, Remarkable History of the Hudson’s Bay Company (1900).

REDRUTH, a market town in the Camborne parliamentary division of Cornwall, England, 17 m. E.N.E. of Penzance, on the Great Western railway. Pop. of urban district (1901) 10,451. It lies high, on the northward slope of the central elevation of the county, with bare rocky moors to the south. It is the chief mining town in Cornwall, and the bulk of the population is engaged in the tin mines or at the numerous tin-streaming works. The parish church of St. Uny, of which only the tower is ancient, stands close outside the town to the west, at the foot of a rugged hill named Carn Brea. On the summit of this hill, besides a monument (1836) to Lord de Dunstanville and a small ancient castle, various prehistoric remains are traceable. A museum attached to the science and art schools and a miners’ hospital are notable institutions in Redruth. A large quantity of the tin is sold by public auction at the mining exchange, the sales being known as tin-ticketings. There are manufactures of safety fuses, breweries, iron foundries and railway works. Tramways serve the neighbouring mines and the small port of Portreath on the north coast.

RED SEA, a narrow strip of water extending S.S.E. from Suez to the Strait of Bab el-Mandeb in a nearly straight line, and separating the coasts of Arabia from those of Egypt, Nubia and Abyssinia. Its total length is about 1200 m., and its breadth varies from about 250 m. in the southern half to 150 m. in 27° 45′ N., where it divides into two parts, the Gulf of Suez and the Gulf of Akaba, separated from each other by the peninsula of Sinai.

The Gulf of Suez is shallow, and slopes regularly down to the northerly extremity of the Red Sea basin, which has a maximum depth of 640 fathoms, and then over a shoal of 60 fathoms goes down to 1200 fathoms in 29° 7′ N. The Gulf of Akaba is separated from the Red Sea by a submarine bank only 70 fathoms from the surface, and in 30° 19′ N. and 34° 43′ E. it attains the depth of 700 fathoms. South of the 1200-fathom depression a rise rises to 500 fathoms in the latitude of Jidda, and south of this again a similar depression goes down to 1100 fathoms. Throughout this northern part, i.e. to the banks of Suakin and Faras in 20° N., the 100-fathom line keeps to a belt of coral reef close inshore, but in lower latitudes the shallow coral region, 300 m. long and 70 to 80 m. across, extends farther and farther seaward, until in the latitude of Hodeida the deep channel (marked by the 100-fathom line) is only 20 m. broad, all the rest of the area being dangerous to navigation, even for small vessels. In the middle of the gradually narrowing channel three depressions are known to exist; soundings in two of these are: 1110 fathoms in 20° N. and 800 fathoms in 16° N., a little to the north of Massawa. To the north-west of the volcanic island of Zebariy the depth is less than 500 fathoms; the bottom of the channel rises to the 100-fathom line at Hanish Island (also volcanic), then shoals to 45 fathoms, and sinks again in about the latitude of Mokha in a narrow channel which curves westward round the island of Perim (depth 170 fathoms), to lose itself in the Indian Ocean. This western channel is 16 m. wide in the Strait of Bab el-Mandeb; the eastern channel of the strait is 2 m. broad and 16 fathoms deep.

Murray estimates the total area at 158,750 sq. m., and its volume at 67,700 cub. m., giving a mean depth of 375 fathoms. Karsten gives the area at 448,810 sq. kilom. (130,424 sq. geographical m.) and the volume at 270,000 cub. m. (35,443 cu. barometric m.), which gives a mean depth of 252 fathoms.

Both these computations, however, were made before the date of the Austrian exploring expeditions (1896–98). Bludau’s measurements give the total area draining to the Red Sea at about 255,000 sq. geographical m. Krümmel’s more recent calculations (see Ocean) give values somewhat higher than those of Karsten.

The Red Sea is formed by a line of fracture, probably dating from Precambrian times, crossing the centre of a dome of Archaean rocks, on both flanks of which, in Egypt and Arabia, rest Secondary and Tertiary deposits. The granite rocks forming the core of the dome appear at the surface on the Red Sea coast, at the western end of the transverse line of heights crossing Nejd. Along the line of fracture traces of volcanic activity are still very evident; many cones, and the high mountains in the north, especially on Jebel Teir, farther north, a volcano has only recently become extinct. The margin of the Red Sea itself consists, on the Arabian side, of a strip of low plain backed by ranges of barren hills of coral and limestone, with some patches of secondary sandstone and some considerable height. The greater elevations are for the most part formed of limestones, except in the south, where they are largely volcanic. The coasts of the Gulf of Akaba are steep, with numerous coral reefs, but those of the Red Sea are low barometric fathoms in the north, wide stretches of desert plain, which towards the south rise to elevated tablelands, and ultimately to the mountains of Abyssinia. The shores of the Red Sea are little indented; good harbours are almost unknown. The only large one is Jidda, on the south side of the strait, the chief inlets are at Massawa, and at Kamaran, almost directly opposite. Coral formations are abundant; immense reefs, both barrier and fringing, skirt both coasts, often enclosing wide lagoons between the reef and the land. The reefs on the eastern side are the more extensive; they occur in places as much as 25 m. from the land. It has long been known that the whole Red Sea area is undergoing gradual elevation, and much has been done recently by investigating the levels of raised beaches found in different localities.

In the northern part, down to almost 19° N., the prevailing winds are north and north-west. The middle region, to 14°–16° N., has variable winds in 17° N., while in the southern Red Sea south-east and east winds prevail. From June to August the north-west wind blows over the entire area; in September it retreats again as far as 16° N., south of which the winds are for a time variable. In the Gulf of Suez the westerly, or “Egyptian,” wind occurs frequently during winter, sometimes blowing with violence, and generally accompanied by fog and clouds of dust. Strong north-east winds prevail for part of the time, and they are weakest in April and May, sometimes giving place at that season to southerly breezes. The high temperature and great relative humidity make the summer climate of the Red Sea one of the most disagreeable in the world.

The annual mean temperature near the head is 77°F.; it rises to 80°F. in about 22° N., to 84°F. in 19° N., and drops again to 82°F. at the Strait of Bab el-Mandeb. Daily variations of temperature are observable to a degree of over 50°F.; but on the whole, higher near the Arabian than the Egyptian side, but it everywhere diminishes with increase of depth and latitude, down to 360 fathoms from the surface; below this depth a uniform constant temperature of 70°F. is observed throughout. In the Gulf of Suez temperature is relatively low, falling rapidly from south to north. The waters of the Gulf of Akaba are warmer towards the Arabian than the Sinaic coast; a uniform temperature of 70°V. is observed at all depths below 270 fathoms.
The salinity of the waters is relatively great, the highest recorded being 42.7 per mille (Gulf of Suez), and the lowest 36.2 (Perim harbour). The distribution is, speaking generally, the opposite to that of temperature; salinity increases from the surface downwards, and from the south northwards, and it is greater towards the western than the eastern side. This statement holds good for the Gulf of Suez, in which the water is much saltier than in the open sea; but in the Gulf of Akaba the salinity is strikingly uniform, nowhere differing much from an average of 40-6 per mille.

The movements of the waters are of great irregularity and complexity, rendering navigation difficult and dangerous. Two factors are particularly effective in this respect— the exchange of water between the Red Sea and the Indian Ocean, and the tidal streams of the Gulf of Suez. From the observations of salinity it is inferred that a surface current runs southward to the eastern channel of the Strait of Bab el-Mandeb, while a very salt water current flows outward to the Indian Ocean, through the western channel, at a depth of 50 to 100 fathoms from the surface. In the Gulf of Suez and Akaba, almost the only part of the Red Sea in which tidal phenomena are well developed, a sharply defined (tidal) circulation is found. Elsewhere the surface movements are at least controlled by the prevailing winds, which give rise in places to complex 'transverse' currents, and near the coast are modified by the channels enclosed by the coral reefs. During the prevalent northeasterly winds the north and northwest winds the surface level of the northern part of the Red Sea is depressed by as much as 2 ft. The great evaporation going on from the surface probably causes a slow vertical circulation of the surface waters, while the saltier waters are sinking, and ultimately escaping to the Indian Ocean. Extensive areas of the deposits forming the bed were made by the expeditions of the Austrian ship "Pola" (1896 and 1898). These were analysed by Dr. Sueda. The conclusions, however, have been disputed by a number of other investigators. Some zoological expeditions show that certain well-defined districts are extremely rich in plankton, while others are correspondingly poor; and it appears that the latter occur in districts surrounded by currents of relatively low temperature, while the former parts are where the movements of water are blocked by irregularities in the coast-line.

REDSHANK, the usual name of a bird—the *Scolopax calidris* of Linnaeus and *Tetanus calidris* of modern authors—so called in English from the colour of the bare part of its legs, which, being also long, are conspicuous as its flies or runs. In suitable localities it is abundant throughout the greater part of Europe and Asia, from Iceland to China, mostly retreating to the southward for the winter, though a considerable number remain during that season along the coasts and estuaries of some of the more northerly countries. Before the great changes effected by drainage in England it was a common species in many districts, but at the present day there are very few to which it can resort for the purpose of reproduction. The body of the redshank is as big as a snipe’s, but its longer neck, wings and legs make it appear more like a heron than a snipe. Above, the general colour is greyish-drab, flecked with black; below, the lower part of the back and a conspicuous band on each wing, which in the lighter, while the flight-quills are black, thus producing a very conspicuous effect. In the breeding season the back and breast are mottled with dark brown, but in winter the latter is white. The nest is generally concealed in a tuft of rushes or grass, a little removed from the wettest parts of the swamp whence the bird gets its sustenance, and contains four eggs, usually of a rather warmly tinted brown with blackish spots or blotches; but no brief description can be given that would point out their differences from the eggs of other birds, more or less akin, among which, those of the lapwing (g.v.) especially, they are taken and find a ready sale.

The name Redshank, prefixed by some epithet as Black, Dusky or Spotted, has also been applied to a larger but allied species—

*the Tetanus fuscescens* of ornithologists. This is a much less common bird, and in Great Britain as well as the greater part of Europe it only occurs on its passage to or from its breeding-grounds, which are usually found south of the Arctic Circle, and differ much from those of its congeners—the spot chosen for the nest being nearly always in the midst of forests and, though not in the same part of them, often with trees on all sides, generally where a fire has cleared the undergrowth, and mostly at some distance from water. This peculiar habit was first ascertained by Wolley in Lapland in 1835 and the following year. The breeding dress this bird assumes is also very remarkable, and seems (as is suggested) to have some connection with the burnt and blackened surface interspersed with white stones or tufts of lichen on which its nest is made—for the bare white shoulders and lower parts are of a deep black, contrasting vividly with the pure white of the back and rump, while the legs become of an intense crimson. At other times of the year the plumage is very similar to that of the common redshank, and the legs are of the same light orange-red. (A. N.)

**REDSHANK,** a bird well known in Great Britain, in many parts of which it is called firetail—a name of almost the same meaning, since "start" is from the Anglo-Saxon *steorl,* a tail. This beautiful bird, *Ruticilla phoenicurus,* returns to England about the middle or towards the end of April, and at once takes up its abode in gardens, orchards and about old buildings, when its curious habit of flitting at nearly every change of position its brightly-coloured tail, together with the pure white forehead, the black throat, and bright bay breast of the cock, while the conspicuous black mottlings cannot be drawn by his lively though intermittent song. The habits of this species are plainly attired; but the characteristic colouring and action of the tail pertain to her equally as to her mate. The nest is almost always placed in a hole of a tree or building, and contains from five to seven eggs of a delicate greenish blue, occasionally sprinkled with faint red spots. The young on assuming their feathers present a great resemblance to those of the redbreast (g.v.) at the same age; but the red tail, though of duller hue than in the adult, forms even at this early age an easy means of distinguishing them. The redstart breeds regularly in all the counties of England and Wales. It also reaches the extreme north of Scotland; but in Ireland it is very rare. It appears throughout the whole of Europe in summer, and is known to winter in the interior of Africa. Several very nearly allied forms occur in Asia; and one, *R. aurore,* in Japan.

A congeneric species which has received the name of black redstart, *Ruticilla titys,* is very common throughout the greater part of the continent of Europe, where, from its partiality for gardens in towns and villages, it is probably better known than the preceding species. It yearly occurs in certain parts near the Channel, chiefly along or near the south coast, and curiously enough, during the autumn and winter, since it is in central Europe only a summer visitor, and it has by no means the high northern range of *R. phoenicurus.* The males of the black redstart seem to be more than one year in acquiring their full plumage (a rare thing in Passerine birds), and since they have been known to breed in the intermediate stage this fact has led to such birds being accounted a distinct species under the name of *R. cairri,* thereby perplexing ornithologists for a long while, though now almost all authorities agree that these birds are, in one sense, immature.

More than a dozen species of the genus *Ruticilla* have been described, and the greater number of them seem to belong to the Himalayan sub-region or its confines. One very pretty and interesting form is the *R. moussetti* of Barbary, which allies the redstart far more closely to the *nome-chats* (see WHEATFAR), and of late some authors have included it in that genus. In an opposite direction the blue-throats, apparently the nearest to the redstart, differ from any other type, are placed in the genus *Cyanecula,* containing two or three distinguishable forms: (1) *C. suecica,* with a bright bay spot in the middle of its clear blue throat, breeding in Scandinavia, Northern Russia and Siberia, and wintering in Abyssinia and India, though rarely appearing in the intermediate countries, to the wonder of all who have studied the migration

1 The orthography of the specific term would seem to be *titis* (Ann. Nat. History, ser. 4, x. p. 227), a word possibly cognate with the first syllable of titlark and titmouse.
of birds; (2) *C. leucocyanaea*, with a white instead of a red gular spot, a more Western form, ranging from Barbary to Germany and Holland; (3) *C. wolfs*, with its throat wholly blue—a form of comparatively rare occurrence. The first of these is not infrequent, though very irregular, visitant to England, while the second has appeared there but seldom, and the third never, so far as is known. The redstarts with their allies mentioned in this article belong to the subfamily Turdinae of the thrushes (q.v.).

In America the name redstart has been bestowed upon a bird which has some curious outward resemblance, both in looks and manners, to that of the Old Country, though the two are in the opinion of some systematists nearly as widely separated from the other as truly Passerine birds well can be. The American redstart, *Setophaga ruticilla*, belonging to the purely New-World family Mniotilidae, and to a genus which contains about a dozen species, having originated from Canada (in summer) to Bolivia. (A. N.)

**RED WING**, a city and the county seat of Goodhue county, Minnesota, U.S.A., on the W. bank of the Mississippi river, near the head of Lake Pepin, about 40 m. S.E. of St Paul. Pop. (1905, state census) 5,419, 2,138 being foreign-born; (1910) 9,048.

It is served by the Chicago Great Western and the Chicago, Milwaukee & St Paul railways. Red Wing is the seat of the Lutheran Ladies' Seminary (1894) and the Red Wing Theological Seminary (Lutheran, 1885), and in the vicinity is the State Training School for Boys and Girls, originally the Minnesota State Reform School. In the city are the Carnegie-Lawther library, a Federal building, a municipal theatre, the T. B. Sheldon Memorial Auditorium, in connexion with which is a School of Music; a Y.M.C.A. building, a City Hospital, St John's (1902) and an old ladies' home. Red Wing is an important wheat market and shipping point.

In 1695 Le Sueur built a post on Prairie Island, in the Mississippi, about 8 m. above the site of Red Wing, for the purpose, according to Charlevoix, of interposing a barrier between the warring Dakotas and Chippewas; and (which is a record of the building at the shore of Lake Pepin) a fort which, after various vicissitudes, was abandoned in 1753.

An Indian village occupied the site of Red Wing probably for many years before the arrival of the first whites, two Swiss missionaries, Samuel Denton and Daniel Gavin, who maintained a mission here in 1837-46. In 1848 another mission was established by the American Board. Red Wing (named from an Indian chief) was platted in 1853 and was chartered as a city in 1857.

**REDWING** (Swed. Rödvings, Dan. Rõddrossel, Ger. Rotdrossel, Du. Koperwette), a species of thrush (q.v.), *Turdus iliacus*, which is an abundant winter visitor to the Brit. islands, arriving in autumn generally about the same time as the fieldfare (q.v.) does. This bird has its common English name1 from the sides of its body, its inner wing-covers and axillaries being of a bright reddish orange, of which colour, however, there is no appearance on the wings themselves while the bird is at rest, and not much is ordinarily seen while it is in flight. In other respects it is very like a song-thrush, and indeed in France and some other countries it bears the name mauvis or mavis, often given to that species in some parts of Britain; but a conspicuous white streak over the eye at once affords a ready diagnosis. The redwing breeds in Iceland, in the subalpine and arctic districts of Norway, Sweden and Finland, and thence across Northern Russia and Siberia, becoming scarce to the eastward of the Yenisei, and not extending beyond Lake Baikal. In winter it visits the whole of Europe and North Africa, occasionally reaching Madeira, while to the eastward it is found at that season in Persia, and, it is said, at times in the north-western Himalayas and Kohat. Many writers have praised the song of this bird, comparing it with that of the nightingale (q.v.); but herein they seem to have been much mistaken as in older times was Linnaeus, who according to S. Nilsson (*Orn. Suecica*, i. 177, note), failed to distinguish in life this species from its commoner congener *T. musica*. Its nest and eggs a good deal resemble those of the blackbird, and have none of the special characters which distinguish those of the song-thrush.

**REDWITZ, OSKAR, FREIDRICH VON** (1823-1801), German poet, was born at Lichtenau, near Ansbach, on the 28th of June 1823. Having studied at the universities of Munich and Erlangen, he was apprenticed to the law in the Bavarian State service (1846-49). He next (1849-50) studied languages and literature at Bonn, and in 1851 was appointed professor of aesthetics and of the history of literature at Vienna. In 1872, however, he gave up this post and retired to his estate of Schellenberg, near Kaiserslautern. The pious sentimentality of his romantic epic *Amaranth* (1849; 42nd ed., 1868) had already gained him enthusiastic admirers, and this work was followed, in 1850, by *Ein Märchen* and *Büdichte* (1852) and the tragedy *Sieglinde* (1854). He next settled on his estates near Kronach, and here wrote the tragedy *Thomas Morus* (1856), the historical dramas *Philippine Welser* (1859) and *Der Zunftmeister von Nürnberg* (1860), of which the first two met with great success. Elected member of the Bavarian Second Chamber for the district in which he lived, he removed to Munich in 1862. In 1868 he published the novel *Herrmann Stark*, *deutsches Leben*, and in 1871 *Das Lied vom neuen deutschen Reich* (which contains several patriotic sonnets). In 1872 he took up his residence at Memminger, but passed the last years of his life at a sanatorium for nervous disorders near Bayreuth, where he died on the 6th of July 1891.

**REED, ANDREW** (1787-1862), English nonconformist divine and philanthropist, was born in London on the 27th of November 1787. He entered Hackney Independent College in 1807 and was ordained minister of New Road Chapel in 1811. About 1830 he built the larger Wycliffe Chapel, where he remained until 1861. He visited America on a deputation to the Congregational Churches in 1834 and received the degree of D.D. from Yale. Reed's name is permanently associated with a long list of philanthropic achievements, including the London Orphan Asylum, the Infant Orphan Asylum and the Reedham Orphanage, which he undertook on non-denominational lines because the governors of the other institutions had made the Anglican Catechism compulsory. Besides these he originated in 1847 an asylum for idiots at Highgate, afterwards moved to Earlswood in Surrey with a branch at Cholchester, and in 1855 the Royal Hospital for Incurables at Putney. He died on the 25th of February 1862. Besides an account of his visit to America (2 vols., 1834), he compiled a hymn-book (1841), and published some sermons and books of devotion.

His second son, Sir Charles Reed (1819-1881), was a successful typefounder and a keen supporter of popular education. As a common councillor of the city of London he developed the Fieldhall Library of the City of London School. He was elected M.P. for Hackney (1868 and 1874) and for St Ives, Cornwall (1880), and served as chairman of the London School Board (1873-1881) in succession to Lord Lawrence. He was interested in antiquarian research and in philanthropic work, being an associate of George Peabody and an active worker in connexion with the Sunday School Union, the Bible Society, the Religious Tract Society and the London Missionary Society. His eldest son, Charles Edward Baines Reed (1845-1884) was

---

1 Many old writers assert that this bird used to be known in England as the "swinepipe"; but, except in books, this name does not seem to the writer to be anything but a popular notion; however, to doubt that it was once in vogue, and the only question is how it may have arisen. If it has not been corrupted from the German *Weidrassell* or some other similar name, it may refer to the noise made with a whistle through an empty tube, resembling the sound of the pipe used by the swineherds of old when collecting the animals under their charge. Another form of the word (which may, however, be erroneous) is "windpipe." "Whindle and wheenerd" have also been given as English names of this bird (*Harl. Miscell.*, 1st ed., ii. 558), and these may be referred to the local German *Weindrassel* and *Wirnsled*.

RED WING—REED, A.
educated at Trinity College, Cambridge, and became Congregational minister at Warminster (1871) and a secretary of the British and Foreign Bible Society. He was killed by a fall in Switzerland. Sir Charles Reed's thir son, Talbot Baines Reed (1852-1893), educated at the City of London School, became managing director of his father's firm, and was one of the founders and secretary of the Bibliographical Society. He is best known as the author of popular boys' books.

REED, ISAAC (1742-1807), English Shakespearean editor, son of a baker, was born on New Year's Day, 1742, in London. He was articled to a solicitor, and eventually set up as a conveyancer at Staple Inn, where he had a considerable practice. His first important work was the *Biographia Dramatica* (2 vols., 1782), consisting of biographies of the dramatists and a descriptive dictionary of their plays. This book, which was an enlargement of David Erskine Baker's *Companion to the Play-house* (2 vols., 1764), was re-edited (5 vols.) by Stephen Jones in 1811, and is a valuable authority. The original work by Baker had been based on Gerard Langbaine's *Account of the English Dramatick Poets* (1601), Giles Jacob's *Poetical Register* (1719), Thomas Whicke's "List of all the Dramatic Authors" (printed with his tragedy of *Sconderbeg*, 1747) and the MSS. of Thomas Coxeter (1686-1747), an industrious antiquary who had collected much useful material. Reed's *Notitio Dramatica* (Addit. MSS. 25390-2, British Museum), supplementary to the *Biographia*, was never published. He revised Dodgson's *Collection of Old Plays* (12 vols., 1780). He also re-edited Johnson and Steevens's edition (1773) of Shakespeare. Reed's edition was published in 10 vols. (1785), and he gave great assistance to Steevens in his edition (1793). He was Steevens's literary executor, and in 1802 published another edition (21 vols.) based on Steevens's later collections. This, which is known as the *first variorum*, was re-issued ten years later. He died on the 5th of January 1807. His valuable library of theatrical literature and manuscript materials was catalogued for sale as *Bibliotheca Reediana* (1807).

See John Nichol's *Lit. Anec. of the 18th Century* (vol. ii., 1812); and Edward Dowden, *Essays, Modern and Elizabethan*.

REED, JOSEPH (1741-1783), American politician, was born in Trenton, New Jersey, on the 27th of August 1741. He graduated at Princeton in 1757, studied law under Richard Stockton and, in 1763-65, at the Middle Temple, London, and practised in Trenton from 1765 until his removal to Philadelphia in 1770. He was president of the second Provincial Congress of Pennsylvania in 1775, was aide-de-camp and military secretary to General Washington in 1775-76, and was adjutant-general with the rank of colonel in 1776-77. He resigned his commission in the autumn of 1777, and in 1777-78 was a delegate to the Continental Congress. From December 1778 to October 1781 he was president of the state Executive Council. During his administration the proprietary right of the Penn family was abrogated (1779), and provision was made for the gradual abolition of slavery (1780). During this time Reed led the attack on Benedict Arnold (q.v.) for the latter's administration of the state Executive Council. Reed was elected to Congress in 1784, but died in Philadelphia on the 5th of March 1785.

The Life and Correspondence of Joseph Reed (2 vols., Philadelphia, 1874), by his grandson, William B. Reed, is based upon the family papers. It pictures Reed as an heroic patriot and statesman; Cassey Bancroft, in the other hand, in the ninth volume (p. 329) of his *History of Pennsylvania* and in Joseph Reed: an Historical Essay (1867), pictures him as a trimmer of the most pronounced type. Bancroft's principal charge against Reed was based on a passage in Count Dornoff's *History of Pennsylvania* (1769), and accused Reed of having engaged in swindling and forgery (q.v.) in 1776. In 1876, however, Mr W. S. Stryker discovered that the reference in the diary was really to Col. Charles Reed (1715-1780). Bancroft withdrew this definite charge in the 1876 edition of his History, in which, however, his tone towards Joseph Reed was unchanged.

Joseph Reed's son, JOSEPH REED (1772-1846), published the *Laws of Pennsylvania* (5 vols., 1822-24), continuing the work of Charles Smith, published in 1810-12, which began with the laws of 1700. His grandson, William Bradford REED (1806-1876), graduated at the university of Pennsylvania in 1822, was a representative in the Pennsylvania legislature in 1834-36, attorney-general of the state in 1838, and a state senator in 1841. He was professor of American history in the university of Pennsylvania in 1830-56, United States minister to China in 1857-58, and in 1858 negotiated a treaty with China, proclaimed in 1860. Besides the biography of his grandfather mentioned above, he published one of Joseph Reed's wife, *Life of Esther De Berdt, afterwards Esther Reed* (1853).

W. B. Reed's brother, HENRY [HOPE] REED (1808-1854), graduated at the university of Pennsylvania in 1825, practised law in Philadelphia, and was assistant-professor of moral philosophy in the university of Pennsylvania in 1831-34 and professor of English literature and rhetoric there in 1835-36. He assisted Wordsworth in the preparation of an American edition of his poems in 1837, edited in America Christopher Wordsworth's *Memoirs of William Wordsworth* (1851), and published *Lectures on English Literature from Chaucer to Tennyson* (1853).

REED, THOMAS BRACKETT (1830-1902), American statesman, was born in Portland, Maine, on the 18th of October 1830. He graduated at Bowdoin College in 1850; was acting assistant-paymaster in the U.S. navy from April 1864 to November 1865; and in 1865 was admitted to the bar. He was a member of the Maine House of Representatives in 1868-69 and of the state Senate in 1870, was attorney-general of the state in 1870-72, and was city solicitor of Portland in 1874-77. He was a Republican member of the National House of Representatives from 1877 until 1899; was a member of the Potter Committee to investigate the disputed presidential election of 1876, and conducted the examination of Samuel J. Tilden; and he was Speaker of the House in 1889-91, and in 1895-99. He was a "strong" speaker in control of the proceedings, and he developed an organized majority on the House Committee on Rules consisting of the speaker and chairman of the committees on ways and means and on appropriations. The "Reed Rules," drawn up by him, William McKinley and J. G. Cannon, were adopted on the 14th of February 1890; they provided that every member must vote, unless pecuniarily interested in a measure, that members present and not voting may be counted for a quorum, and that no dilatory motion be entertained by the speaker. His parliamentary methods were bitterly attacked by his political enemies, who called him "Tsar Reed." He greatly hastened the passage of the McKinley Bill in 1890, and of the Dingley Bill in 1897. His rules and methods of control of legislation were adopted by his successors in the speakership, and the power of the Rules Committee was greatly increased under Charles F. Crisp (1845-1896), Democratic speaker in 1891-1893. After the war with Spain Reed broke with the administration on the issue of imperialism. He resigned his seat in 1890 and practised law in New York City. He died in Washington on the 7th of December 1902. Reed was a remarkable personality, of whom many good stories were told, and opinions varied as to his conduct in the chair; but he was essentially a man of rugged honesty and power, whose death was a loss to American public life.

Reed's *Rules* were published as a parliamentary manual. He edited with others *A Library of Modern Eloquence* (10 vols., 1901). See the chapter on Reed in H. B. Fuller's *Speakers of the House* (Boston, 1899).

REED, a term applied to several distinct species of large, water-loving grasses. The common or water-reed, *Phragmites communis*, (also known as *Arundo phragmites*), occurs along the margins of lakes, fens, marshes and placid streams, not only throughout Britain, but widely distributed in arctic and temperate regions. Another very important species in *Ammophila arenaria* (also known as *A. arundinacea* or *Palamena arenaria*), the sea-reed or marram-grass, a native of the sandy shores of Europe and N. Africa. Both species have been of notable geological importance, the former binding the soil and so impeding denudation, and actually converting swamp into dry land, largely by the
aid of its tail (5 to 10 ft.) close set stems. The latter species, of which the branching rootstocks may be traced 30 or even 40 ft., is of still greater importance in holding sand-dunes against the sea, and for this purpose has not only been long protected by law, but has been extensively planted on the coasts of Norfolk, Holland, Gascony, &c. Other reeds are Calamagrostis (various species), Glyceria argenteum (pampas grass), Deyeuxia, &c., also Arundo Donax, the largest European grass (6 to 12 ft. high), which is abundant in Europe. Reeds have been used from the earliest times in thatching and in other branches of construction, and also for arrows, the pipes of musical instruments, &c. Reed pens are still used in the East. Plants belonging to other orders occasionally share the name, especially the bur-reed (Spartium) and the reed-mace (Typha), both belonging to the natural order Typhaceae. The bulrushes (Scirpus), belonging to the natural order Cyperaceae, are also to be distinguished.

**REEDBUCK** (Dutch riebok), the popular name of a foxy red South African antelope (Cercopitta arundinum) of medium size, with a moderately long bushy tail, a bare gland-patch behind the ear, and in the male rather short horns which bend forwards in a regular curve. There are several other species of allied African antelopes included in the genus *Cercopitta* to which the name of reedbuck is also applied, one of these ranging as far N. as Abyssinia, and another inhabiting W. Africa.

**REED INSTRUMENTS** (Fr. instruments à anche; Ger. Blase-instrumente mit Zungen; It. Strumenti aancia), a class of wind instruments in the tubes of which sound-waves are generated by the vibrations of a reed mouthpiece. Reed instruments fall into two great classes: (1) those blown directly by the breath of the performer, who is thus able in all but a few obsolete instruments to express his emotional feelings in music; (2) those in which the wind supply is obtained by mechanical devices, such as the bag of bagpipe instruments or the bellows of such keyboard instruments as the regal, harmonium and kindred instruments.

Directly-blown reed instruments comprise the section of modern wind instruments known as the “wood wind,” with the exception of flute and piccolo; they are classified according to the kind of reed vibrator of which the mouthpiece is composed. There are three kinds of reed mouthpieces: (1) the single or beating reed; (2) the double reed; (3) the free reed, all of which perform the function of sound-producer (see MOUTHPIECE and FREE REED VIBRATOR). The reed used consists of a thin tongue or strip of reed, cane or some elastic material, thinned gradually to a delicate edge. It is adapted to a resonating tube in such a manner that when it is at rest the opening at the mouthpiece end of the tube consists only of a very slight aperture or chink, which is periodically opened and closed by the pulsations of the reed when acted upon by the compressed breath of the player. This principle is common to all reed mouthpieces, and the difference in timbre is in a measure due to the manner in which the pulsations are brought about and the degree of elasticity secured.

The **double reed** consists of two blades of reed or laminae of elastic material tightly bound together by many turns of waxed silk, so that above the construction the tube has an oval section; below, where it communicates with the main bore of the instrument, the tube is strictly cylindrical. The chink here is formed by two thin walls of reed of equal elasticity (see OBOE, BASSOON). The double reed is common to the members of the oboe family, consisting, besides the oboe, of the cor anglais or tenor, of the fagotto or bassoon, and of the contra fagotto or double bassoon. The double reed mouthpiece is used besides on the sarrusophone family, instruments of brass but classed with the wood wind on account of the mouthpiece and fingering.

The **single or beating reed** consists of a single blade bevelled at the edge and placed over a table or frame communicating with the main bore of the instrument, against which it beats, causing a series of pulsations. The single reed is common to all the members of the clarinet family, consisting, besides the clarinet, of the basset-born or tenor, and of the bass and pedal clarinets; of the batyphone, an early bass clarinet, and of the saxophone, a metal oboe with a beating reed instead of a double reed. The ancient Greek aulos was undoubtedly used with a beating reed during some period of its history.

The **free reed** is not represented among members of the modern wood wind, and, as adapted to a directly-blown instrument, only finds application in the Chinese cheng, the prototype of the harmonium, and in the mouth organ or harmonica.

The reed in wind instruments produces a peculiar tone quality to which it has given its name; it varies in the three different kinds of mouthpieces without losing the fundamental reedy timbre. In the single reed the impact against the hard wood of vulcanite of the table against which it beats produces a sound harsh and strident in inverse proportion to the degree of elasticity possessed by the vibrating tongue. In the clarinet the reed is carefully and delicately made of cane with due regard to the interdependence of reed and clarinet tube. The strong wooden or metallic beating reeds of the early organ reed pipes must have had an unpleasantly harsh timbre, which won for them in Germany the epithet Schnarrwerk.

In the double reed the two delicately shaped pieces of reed vibrate against each other, producing the somewhat nasal, reedy tone of the oboe family. In the free reed compressed air is the only buffer which the vibrater encounters while swinging through the aperture, alternately closing and reopening it; hence the soft and mellow timbre which it is possible to produce by proper treatment of the free reed. Experience has shown that the best results for the double reed are obtained when it is used in conjunction with a tube of conical bore, whereas the beating reed is heard to greater advantage in instruments with cylindrical bore, one notable exception in practice being as already mentioned, the saxophone family. The double reed adapted to a conical tube confers upon the latter the acoustic properties of the open pipe, whose wave-length is equal to that of the tube and which is capable of overblowing the octave and successive harmonics (theoretically). Either a single or a double reed adapted to a cylindrical pipe converts it for all acoustic purposes into a closed pipe, in which the whole wave-length is twice the length of the tube, a node forming at the mouthpiece end. The fundamental note of such a tube will therefore be an octave lower than that of an open pipe of the same length, and it can only overblow the uneven numbers of the harmonic series, such as the third harmonic (or twelfth above the fundamental).

In order to overblow on instruments with reed mouthpieces, greater pressure of breath must be exerted, and the vibrating length of the reed must be decreased by the action of the lips upon it. This is what occurs in instruments of the oboe and clarinet type, which are blown directly from the mouth. There are, however, cases in which the reed is concealed within the instrument out of reach of the lips, either in a capsule, as in the old instruments hautbois de Poitou and cromorne, or else in a socket, as in the chunter and drones of the bagpipe, or, again, as in the mouthpieces of organ reed pipes. In the last (each of which gives but one fixed note) the vibrating length of the reed tongue is fixed, as is also the pressure of the compressed air supply fed to them. The result in all these cases is similar: no harmonics can be obtained, and therefore the scale of the instrument depends solely on the number of holes and keys provided, whereas, where the lips control the reed, fewer holes are necessary to produce a given compass. The counters of bagpipes have double reeds, but the drones are as a rule provided with beating reeds and are of cylindrical bore, a combination which, for the reason explained above, gives them a note an octave deeper in pitch, the length of pipe being equal, than would be the case if the bore were conical. In the musette, in the cornemuse used in concert with the hautbois de Poitou, and in the Neapolitan surdelina (see BAGPIPE), both chunter and drones had double reeds.

The auloi of the ancient Greeks and tibia of the Romans consisted in the older instruments of a cylindrical tube of very narrow
REEF—REEVE

bore, which facilitated the production of the harmonics. The
aulos, though often erroneously translated flute, was an oboe or
clarinet. Writers on musical instruments are not agreed as to
which mouthpiece was in use on the aulos; the probability is
that it was a reed mouthpiece in some time; but as far as the
reed, being the most primitive and also the more adaptable, was
the older contrivance. There is no sign of any suitable attach-
ment for a beating reed on any of the pipes of ancient Greece except,
where the party pipes from Pompeii there is a fragment which may have been a beak mouth-
piece with beating reed similar to that of the modern clarinet.
The ancient Egyptians used the primitive beating reed familiarly
known in our day.1 It was obtained by cutting a slight slant across
a reed pipe or stem of straw, and with the knife splitting
back longitudinally until a tongue was raised; the shorter the
tongue the quicker the vibration and the higher the pitch. This
small beating reed was doubtless used both in Egypt and Greece.
Such reeds were found in tombs by Professor Flinders Petrie.
It is certain that the ancient Greeks did not use the reed in this form in the aulos, for
classical writers distinctly describe the effect produced on a reed
by taking it into the mouth, but it is equally certain that they
were acquainted with the principle of the drone.
The history of the keyboard instruments furnishes instances of
the early use of reeds. In the modern English church organ
the reed work is provided with beating reeds only, but in Germany,
for the sake of obtaining the power of expression, a set of free-reed
stops is nearly always added.2 It is probable that some of the early
pneumatic and hydraulic organs of ancient Rome (AUGAN) at
the beginning of the Middle Ages were fitted with beating reeds in imitation of the
bagpipe chanter and drones. In the middle ages the regal
(geflöß), a small, portative reed-organ fitted with beating reeds,
was extremely popular in England and found its way to the Continent and Rome,
but more particularly in Germany and Italy.

REEF (i) (Du. rif, cf. Ger. Riif, Swe. rej, rö, all from O.
Norr. ríf, rib), in physical geography, a narrow ridge of rock,
shingle or sand culminating at or near the surface of the
sea. In a transformed sense the word is used in mining of a vein or
lode of gold-bearing quartz; (ii) (Du. reif, rief, cf. Ger. Reif, Swe.
Rejd, rib, the same or a transferred sense of rif, rib), part
of a sail which can be rolled or folded up, thus diminishing the
amount of canvas spread to the wind. In square sails, "reefs"
are taken from the top, in fore-and-aft sails from the foot.

REEL (O. E. hreol, glossed by the Med. Lat. alibrum
in Aelfric's Glossary, c. 1050; the word is of unknown origin;
it does not appear in cognate languages, and Celtic forms such as
Gaelic ruadhail are from English), a cylinder or apparatus of
cylindrical shape on which a thread or line can be wound; e.g.,
the small wooden cylinder with projecting rings at either end
on which sewing cotton or silk is wound for immediate use,
the revolving "click-reel" attached to a fishing-rod, and the
open revolving framework on which thread is wound as it is
spun. The name of the Scottish dance (Gaelic ríghil, ríuilh,
ruadhail) is probably the same word (see Davve).

REES, THOMAS (1777–1854), Welsh Nonconformist
divine, was born at Lligirion, Glamorgan, and educated at the
Presbyterian College, Carmarthen. He entered the Unitarian
ministry in 1807 at Newington Green Chapel, London, removing
to Southwark 1813 and to Stamford Street, Blackfriars, in 1823.
He had the degree of L.L.D. of Glasgow (1810). He had a
great knowledge of the history of anti-trinitarian opinion,
especially during the 17th century. His scattered papers,
chiefly in the Monthly Repository (1818–22), on such subjects as
"Faustus Socinus and Francis David," "The Italian Reforma-
tion," "Memoirs of the Socini," are important. Financial
troubles drove him to Spain in 1833, and he died in obscurity
at Brighton on the 1st of August 1846.

Robert Reeve (1811–1858), a native of Pen-
Pontbren, Carmarthenshire, held pastures at Aberdare
(1840), Llanelly (1842), Cendwl, Mon. (1849) and Swansea (1862),
and became chairman of the Congregational Union of
England and Wales, but died just before his term of office was to begin.
His History of Protestant Nonconformity in Wales (1861; 2nd ed.
1883) is a sound and judicious piece of work.

REEVE, CLARA (1729–1807), English novelist, daughter of
William Reeve, a Suffolk clergyman, was born at Ipswich in 1729.
She was an industrious writer, and produced many works in
prose and verse, including a history of the Progress of Romance
(1785); but her only eminent success was the novel of The Old
English Baron (1777), originally published under the title of
The Champion of Virtue. In the history of the English novel
she stands midway between Walpole and Mrs. Radcliffe. She
died at Ipswich on the 3rd of December 1807.

REEVE, HENRY (1813–1871), English publicist, younger
son of Henry Reeve, a well-known Whig physician and writer of
Norwich, and nephew of Mrs. Sarah Austin, was born at
Norwich, the 9th of September 1813. He was educated at the
Norwich grammar school under Edward Valpy. During his
holidays he saw a good deal of the young John Stuart Mill. In
1829 he studied at Geneva and mixed in Genevan society, then
very brilliant, and including the Sismondins, Huber, Bonstetten,
De Candolle, Rossill, Krasinski (his most intimate friend), and
Mickiewicz, whose Faris he translated. During a visit to
London in 1831 he was introduced to Thackeray and Carlyle,
while through the Austins he made the acquaintance of
other men of letters. Next year, in Paris, he met Victor Hugo,
Cousin, and Scott. He travelled in Italy, sat under Schelling
at Munich and under Tieck at Dresden, became in 1833-35 a
frequenter of Madame de Circourt's salon, and numbered among
his friends Lamartine, Lacordaire, De Vigny, Thiers, Guizot,
Montalembert, and De Tocqueville, of whose books, Démocratie
en Amérique and the Ancien régime, he made standard trans-
lations into English. In 1837 he was made clerk of appeal
and then registrar to the judicial committee of the Privy Council.
From 1840 to 1855 he wrote for The Times, his close touch
with men like Guizot, Bunsen, Lord Clarendon, and his own chief
at the Privy Council Office, Charles Greville, enabling him to
write with authority on foreign policy during the critical period
from 1848 to the end of the Crimean War. Upon the promotion
of Sir George Cornewall Lewis to the Cabinet early in 1855
Reeve was asked by Longman to edit the April number of the
Edinburgh Review, to which his father had been one of the
coldest contributors, and in the following July he became the
editor. His friendship with the Orleanist leaders in France
survived all vicissitudes, but he was appealed to for guidance
by successive French ambassadors, and was more than once
the medium of private negotiations between the English and
French governments. In April 1863 he published what was
perhaps the most important of his contributions to the
Edinburgh—a searching review of Kinglake's Crimee; and in 1852
he brought out a selection of his Quarterly and Edinburgh
articles on eminent Frenchmen, entitled Royal and Republican
France. Three years later appeared the first of three instal-
ments (1875, 1883 and 1887) of his edition of the famous
Memoirs which Charles Greville had placed in his hands a few
hours before his death in 1865. A purist in point of form and
style, of the school of Macaulay and Milman, Reeve outlined
his literary generation, and became eventually one of the most
reactive of old Whigs. Yet he continued to edit and upon
the whole to maintain the reputation of the Edinburgh until
his death at his seat of Foxholes, in Hants, on the 21st of
October 1895. He had been elected a member of "The Club"
in 1861, and was made a D.C.L. by Oxford University in 1869,
a C.B. in 1871, and a corresponding member of the French
Institut in 1866. A striking panegyric was pronounced upon
him by his lifelong friend, the duc d'Artois, before the
Académie des Sciences in November 1895.

His Memoirs and Letters (2 vols., with portrait) were edited by
Sir J. K. Laughton, in 1898.

REEVE (O. E. gerefa), an English official who in early times
was entrusted with the administration of a division of the
country. He was the chief magistrate of a town or district,
and is the ancestor of the sheriff, the shire-reeve. In addition to the sheriff there were several kinds of reeves, and we are told in the body of laws known as the laws of Edward the Confessor that it is "multiplex nomen; greve enim dicitur de scira, de wapentagiis, de hundredis, de burgis, de villis." Thus we hear of port-reeves, burg-reeves, and tun-reeves, while the Anglo-Saxon Chronicle mentions high reeves. It was the tun-reeve or reeve of the township who with four other men represented the township in the courts of the hundred and the shire. In free townships he was probably chosen by the inhabitants; in dependent townships by the lord. A little later there were manor reeves, these being elected by the villains; according to Fleta, their duties were to attend to the cultivation of the land, and to see that each villain performed his proper share of service. The reeve of Chaucer's Canterbury Tales was doubtless a steward or bailiff, something equivalent to the grieve in Scotland to-day.

In early English the word reeve was sometimes used as a translation for the prefect or governor of Roman and Jewish times. Some authorities have thought that there is some connexion between the Anglo-Saxon gerefa and the German Graff, but Max Müller (Lectures on the Science of Language, 1885) is inclined to doubt this. J. M. Kemble (Saxons in England, 1876), who goes at length into the history of the reeve, connects the word with rõfan or réfan, to call aloud, this making him the original of the bannitor, or proclaimer of the court. At the present time the word reeve is sometimes used to describe a foreman or overseer in a coal mine. It is also used in Canada for the president of a village or town council.

REEVES, JOHN SIMS (1818-1900), English vocalist, was born at Woolwich on the 26th of September 1818, and received his musical education from his father, a musician in the Royal Artillery. At the age of fourteen he had progressed so far as to be appointed organist of North Cray church, and could play the oboe, bassoon, violin, and violincello. He seems to have studied medicine for a year, but changed his mind when he gained his adult voice: it was at first a baritone, and he made his earliest appearance at Newcastle in 1839 in various baritone parts. He studied with Hobbs and T. Cooke, and, his voice having become a tenor, he appeared under Macready's management at Drury Lane (1841-43) in subordinate tenor parts in Purcell's King Arthur, Der Freischütz, and Acis and Galatea, when Handel's pastoral was mounted on the stage with Stanfield's scenery. Four years were spent in study on the Continent, under Bordogni in Paris and Mazzucato in Milan, and his début in Italian opera was made at the Scala as Edgardo in Lucia. He reappeared in London in May 1847 at a benefit concert for Vincent Wallace, and at one of the Ancient Concerts in the following month, his career on the English operatic stage beginning at Drury Lane in December 1847 in Lucia, under the conductorship of Hector Berlioz. In Balfe's Maid of Honour he created the part of Lyonnell in the same season. In 1848 he went to Her Majesty's Theatre, singing in Linda di Chamounix; and in the autumn of that year, at the Norwich Festival, made a great sensation in "The enemy said," from Israel in Egypt, a song in which the finest qualities of his ringing voice could be appreciated. From his first appearance at the Sacred Harmonic Society in the following November he was recognized as the leading English tenor; and in Costa's Eli and Naaman the tenor parts were written for him. His first Handel Festival was that of 1857, and the effect of his wonderful declamation in the Crystal Palace was a main attraction of this and of many subsequent festivals. His retirement from public life, at first announced as to take place in 1882, did not actually occur till 1891, when a farewell concert for his benefit was given at the Albert Hall. His savings were invested in an unfortunate speculation, and he was compelled to reappear in public for a number of years. He died at Worthing on the 25th of October 1900.
